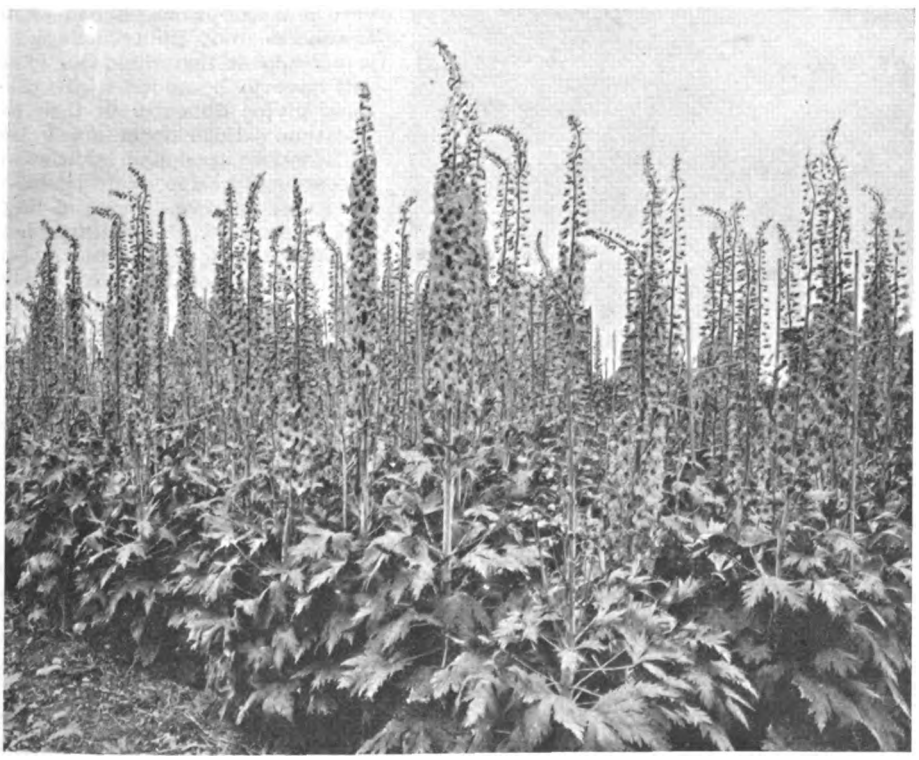
Two visits, with an interval of ten days between, sufficed to inspect almost every variety grown at somewhere near its best, but the would-be planter will do well to bear in mind that some varieties produce their main show of blossom appreciably earlier than others. This is a matter of real importance where colour harmonies are being worked out. It is, in fact, good policy for this particular purpose to visit a first-rate collection when the plants are in flower and to select sorts which are at the time in a similar stage of development. It should be tolerably simple too, to thus get any desired combinations of colouring, which, from a catalogue, is by no means easy, for descriptions such as "blue and purple," give little indication of the general colour effect as seen from a little distance; so much depends upon the exact proportioning of the colours in the blossom.

The outstanding feature of a really splendid collection is the group of "Wrexham" sorts with their immense and perfect spires of loosely-arranged blossoms, but the older stock-flowered forms are also largely grown, and their comparative value can easily be judged. At the time of my first visit a number of immense spikes of the soft blue and mid-mauve Advancement formed, no doubt, the *pièce de résistance*. The plants were all between 6ft. and 6ft. 6ins. tall, of which quite 3½ft. represented the spike of blossom, some 8ins. through at the base and tapering almost to a point, with the individual blossoms up to 2½ins. across. Many dozens of flowers were fully expanded at once on each spike, though not in the least bit crowded. Advancement is a good name for the variety, and the colouring is very pleasing, though by no means an unusual one for the flower.

Quantities of the blue-purple, white-eyed The Bishop and of Coquette, with conspicuous patches of gentian blue on the reddish violet blossoms, served to demonstrate the garden value of two of the very best of recent introductions, while Novelty, gentian blue, toned purple and with a conspicuous dark "bee," and a symphony of soft blues and lilacs called Lovely, were, each in its own way, irresistible.

Others specially noted on this occasion were Theodora, a tall, bright blue of Belladonna strain; Orpheus, of almost lilac pink colouring; the nearly indigo Smoke of War; the pinkish mauve Le Danube, and the now well known clear pale blue Mrs. Townley Parker. Lord Curzon, lavender, also appealed, and, of the older sorts, King Bladud and The Alake have still, apparently, power to compel a pause for admiration.

Perhaps the most telling bits of colour noted on this occasion were provided by these well named varieties, Blue Bird and Evening. The former, though a fairly tall grower and very free-flowering, does not throw spikes comparable in size with those of Mrs. Townley Parker—leaving aside the immense spires of the Wrexham sorts—but the colouring, a really brilliant gentian blue makes it quite invaluable for the border.



A FINE BED OF COQUETTE, ONE OF BEST OF RECENT INTRODUCTION,

THE HELIO-MAUVE VARIETY JOY BELLS.

Digitized by Google

Seen at midday the variety Evening might be described by the usual " tones of blue and purple," but as, long before sunset, the violet rays of the sunlight begin to fail, the spikes take on a tone of royal purple unmatched in any other flower known to the writer. As the spike is a really good one and the daylight colouring of quite average value, this is a very suitable variety for any herbaceous border, but it will make its main appeal to those who keep a special corner for the many flowers which reserve their most attractive aspect for eventide.

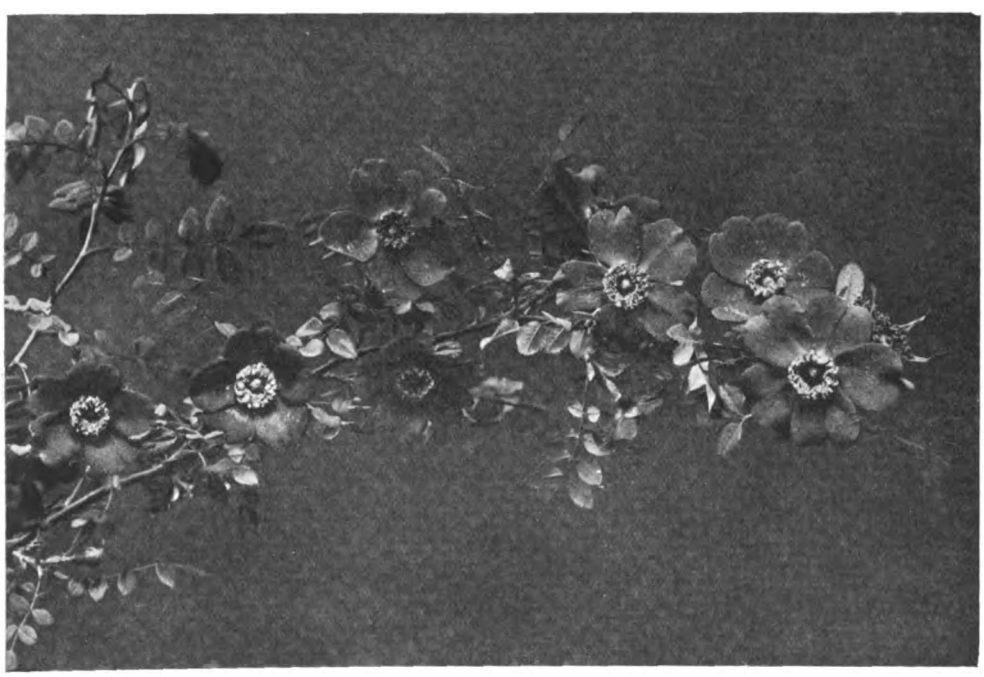
On my second visit I found many of the varieties already noted still in the best of condition, though naturally many fine spikes had been cut for exhibition purposes. The stately Monarch of Wales was now nearing its best and the very numerous plants of this white-eyed giant were a picture worth going far to see. The general colouring is mauve, set against a background of gentian blue. Equally attractive and certainly more unusual in colouring, is Violet Queen, of very violet tone, also contrasted with deep gentian blue—a very handsome and distinct variety. The helio-mauve Joy Bells appropriately enough introduced a calm battalion of Happy Thoughts. Queen Mauve, of pale, clear mauve colouring, with a backing of soft blue, is already an established favourite with those ladies who have made her acquaintance.

Perfectly formed spikes of almost clear pink—clear pink it is towards nightfall—each petal neatly tipped with Belladonna blue and centred with a khaki bee, represented the variety Venus, which will not be on offer this season. The flowers, though not gigantic, are of perfect form and finish, and their arrangement on the rather narrow spire is exquisite. On the whole I believe I covet a stock of this variety more than any other the firm has to show, though they have some really splendid sorts coming on of their own raising. It is useless to describe them, as they are still under number. The quality of the seedlings each year is such that the selection of half a dozen or so of the best and most distinct must be a very trying and unenviable task. SUSSEX.

SOME CHINESE SHRUBS & TREES of our GARDENS

(*Concluded from page 552.*)

AMONG hardy evergreen trees and shrubs grown for foliage effect, Magnolia Delavayi stands almost unrivalled, with its leathery leaves, which attain up to rather over 1ft. in length and 6ins. to 8ins. wide. It forms a most effective subject when grown as a single specimen upon a lawn, although it would probably display its creamy white flowers earlier if planted against a warm wall in a position similar to that in which is usual to plant M. grandiflora. It should be so planted that it is sheltered from the prevailing winds, as its large, handsome leaves are liable to be torn.



ROSA MOYESII, A HANDSOME WILD ROSE FROM THE EAST.

The well known M. conspicua, the yulan or lily tree, is a deciduous representative from China, where it has long been cultivated.

The osmanthus is a genus of evergreen shrubs bearing a rather close resemblance to the holly. The one that is becoming the most widely planted is Osmanthus Delavayi, a charming shrub with small, dark green leaves, producing in March and April clusters of sweetly scented white jessamine-like flowers. As with many early-flowering shrubs, its great disadvantage is its liability when in full flower to become damaged by spring frosts. One occasionally sees a specimen at this season of the year whose petals have been badly marred and mottled by the action of frost. The difficulty regarding any early-flowering subject liable to damage in this way may best be overcome by planting in a westerly border, thus avoiding the rays of the early morning sun and allowing the thaw to take place gradually.

There are two poplars, introduced by Wilson from China, which are both distinct and handsome and of outstanding beauty, Populus lasiocarpa and P. Wilsoni. Both are comparatively rare, and will probably remain so for some long time to come owing to the difficulty they give in their propagation. This genus, with but very few exceptions, is one of the easiest to root from cuttings. It would appear that these two species will have to be added to the list of those giving difficulty in their propagation. Both form small trees with widely spreading branches and exceptionally large ovate leaves, up to 10ins. or even more in length and 8ins. wide. P. lasiocarpa has a prominent red petiole and mid-rib. P. Wilsoni differs in the colour, texture and shape of the leaf, and also by the purplish green, glabrous branchlets. The leaf of the latter is not so cordate at its base as in the former case.

The vastness of the rhododendron genus makes it impossible to select even some two or three species and describe them as being the most noteworthy of the genus. This family probably contains the greatest number of our most beautiful flowering trees and shrubs hardy in this country. The number of Asiatic species is now very nearly a thousand which should provide a sufficient selection for any purpose and situation.

EASTERN ROSES.

It would occupy many pages to describe adequately the Chinese members of the genus Rosa. Rosa Hugonis is one of the most graceful and beautiful, with its long, arching branches covered with pale yellow flowers, which are about 2½ins. in diameter. R. omeiensis is a vigorous shrub bearing small white flowers in profusion; the stems are thickly set with finely pointed thorns. The bright red, elongated fruits borne upon fleshy yellow stalks are very showy. Wilson, in speaking of this rose, says it is common on the mountains of western China at altitudes of 6,000ft. to 11,000ft. above sea level, and sometimes grows 20ft. tall and forms great thickets. The name is derived from one of the sacred mountains of China, Mount Omi, where it is common. The variety pteracantha differs from the type in its large red, translucent spines, which are a curious attraction of this plant. They more resemble the fins of a fish than the thorns of a rose.

Digitized by Google

R. Moyesii, with its large, single, crimson flowers, followed in the autumn by elongated pear-shaped fruits of 1½ins. or more long, is a magnificent addition to our rose gardens.

R. Willmottiæ is equally beautiful when covered with its delicate lilac blossoms. Perhaps the finest pink-flowered species is R. macrophylla or R. setipoda.

Sorbus munda subarachnoidea forms a very handsome small tree, and may perhaps best be likened to a white-fruited rowan or mountain ash. Its compound fern-like leaves and its corymbose clusters of pearl white fruits are the outstanding features of this rare and attractive plant. The comparatively juvenile state at which it attains perfection is a useful and uncommon attribute. Here a young specimen still less than 6ft. high has flowered and fruited profusely for the past two years.

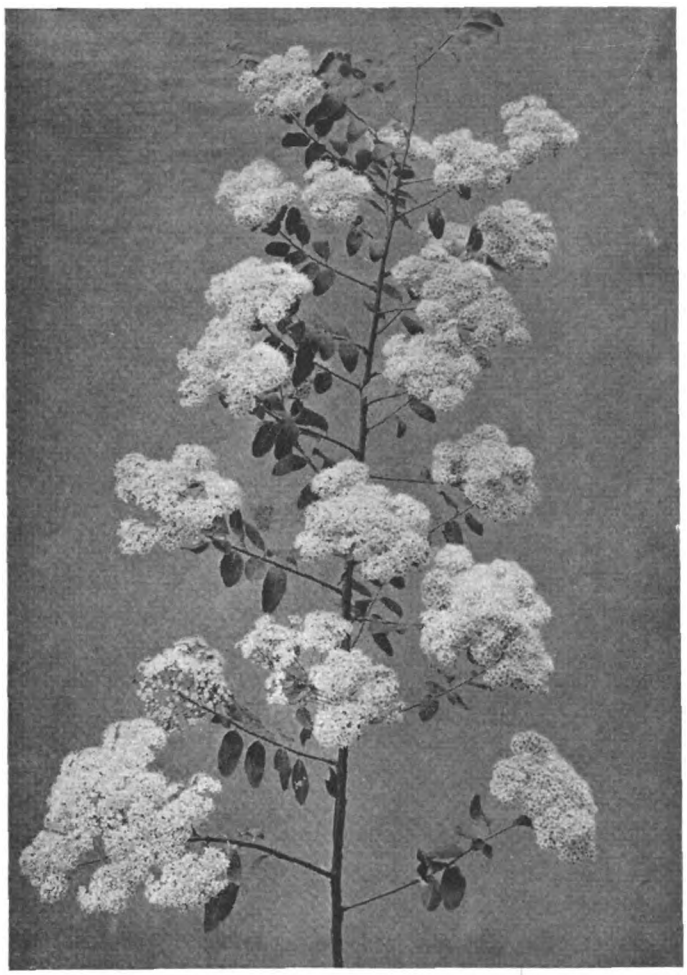
The genus spiræa is a very large one, embracing both herbaceous and woody species. The latter vary from small alpines of a few inches high to shrubs of tree-like dimensions. Although of wide distribution, there is no woody species native to this country. Spiræa arborea (Sorbaria arborea) in its several forms is one of China's giant species, attaining 30ft. in height; it is most closely related to the better known S. Lindleyana. It bears paniculate clusters of white flowers, the inflorescence being often 18ins. or more across; its large compound leaves are also strikingly handsome.

S. Veitchii is one of the latest of the shrubby species to flower. It is a shrub from 8ft. to 10ft. high, with numerous stems and gracefully arching branches, which by the middle of July are covered with broad, white, flower clusters raised on erect stems.

A glance at Salix magnifica would at once give a casual observer the impression that they were looking at a magnolia or any other genus rather than a willow. This, however, is not to be wondered at, since Wilson told me that when he first saw this plant wild in China he himself thought that it was a magnolia and it was not until he noticed the drooping catkins that he realised he had discovered a willow, the appearance of which differs in an extraordinary manner from any other of the genus. Leaves may frequently be seen up to 8ins. or even 10ins. long and half as wide.

Stranvæsia undulata, allied to the photinias, is a most useful evergreen, mainly on account of the profusion of its fruits in the autumn. There appear to be three forms of this species, one of slow spreading, somewhat prostrate habit of growth, and another of more rapid and fastigiate form. The leaves of the former are usually more undulate in margin. Both bear clusters of fruit of a bright scarlet colour. The third form differs in the colour of the fruit, which varies from a pale greenish lemon yellow to a good shade of orange.

The genus syringa, commonly known as lilac, has several very fine species native to China. Syringa reflexa, with its drooping panicles of rose-coloured flowers, and S. Wilsoni, with its less dense, non-pendulous panicles of similar coloured flowers, are two of the best. S. Giraldi and S. pinnatifolia are always the first lilacs to open. The former bears lilac-coloured flowers and the latter white flowers with compound leaves not unlike those of a mountain ash.



THE BROAD WHITE FLOWER CLUSTERS OF SPIRÆA VEITCHII.

CHINESE VIBURNUMS.

Chinese viburnums are among the most ornamental of our flowering shrubs. As a genus viburnum possesses great variety, and many of the species have the most esteemed plant qualities—hardiness, conspicuousness and fragrance of flowers, with distinct foliage and coloured fruits. With possibly the one exception of V. alnifolium all the species thrive on chalky soils. V. Carlesii, with its sweetly scented flowers opening before the foliage, is perhaps at present the most popular of the Chinese species. Very similar to this when in flower is V. fragrans, of which the late Reginald Farrer wrote "it may be seen in every yard of temple and palace and humblest cottage court in Kansu and Thibet." This is one of the earliest of shrubs both to flower and come into leaf. V. Henryi, with its narrow oval leaves up to 5ins. in length, when covered with fruit, which is at first red, ultimately black, is an attractive evergreen.

Another distinct evergreen is V. rhytidophyllum, with its large dark green leaves, whitish on the underside, and with fruit similar in colour to that of V. Henryi. The disadvantage of this otherwise remarkable shrub is in its appearance during rough weather. Both during frost and wind its leaves hang down in such a manner as to appear wilted. When given favourable conditions, that is, a sheltered situation, it is certainly one of the most noble foliage plants which thrive on chalk soils.

V. Davidii is another evergreen species, but of dwarfer habit than the above mentioned. Its great acquisition is its turquoise blue fruits.

H. G. HILLIER.

SERVICE FOR READERS

Though so many subjects are dealt with in each issue of THE GARDEN, it must constantly happen that readers seek information which is not immediately available. In such circumstances they should make use of our new Service Department. Through its medium each reader's own particular enquiry can be dealt with. No matter what the question is, whether advice is sought as to—

RESTOCKING A GARDEN, COLOUR SCHEMES FOR GARDENS, THE BEST PLANTS FOR CERTAIN SITUATIONS, WHERE TO OBTAIN NEW AND RARE PLANTS, INSECT PESTS, NAMING OF PLANTS, AND THE HUNDRED AND ONE OTHER DETAILS RELATING TO THE GARDEN—

there is always information available from a staff of expert contributors and consultants; *and there is no charge for this.* It is one of the additional means of Service which THE GARDEN is glad to render to its readers.

Also, there is the further convenience which the Service Department affords of supplying readers with data about anything that is advertised in the pages of the paper. Thus, on receipt of an enquiry, particulars will be sent of, say, half a dozen things about which the reader seeks information. The only stipulation is that a stamped addressed envelope shall be sent with the enquiry.

All communications should be addressed to the Service Department, THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C.2.

NOTES OF THE WEEK

A NOTE ON SOME MOUNTAIN FLAXES.

I DO not know why Linum tenuifolium is described in an up-to-date handbook as a rare new species, as it is widespread throughout the Alps, and its identity as a distinct species was never in question. Probably it has not come into general cultivation on account of its straggly habit and its colour—which is pale mauve and inferior to the opaque light sky blue of L. alpinum. Botanically it is distinct from alpinum mainly by being downy in part and by its thinner pointed sepals and petals, the petals of alpinum being full and rounded. The colour and habit of both are far surpassed by L. austriacum, which has not yet found its way into catalogues but is successfully grown in gardens here and there. In nature I know of austriacum in a few places only, far apart: the Ligurian Alps, the mountains round Garda, and here and there among the hills of Greece. It is close to L. alpinum except in its impressive deep substantial azure and its more compact and stiffer habit. Mr. Farrer stated that it belonged to higher altitudes than L. salsoloides, and yet it was less hardy. But, actually, L. austriacum descends to the Mediterranean seashore and is very abundant on that botanically wonderful cape, the Capo di Noli, near Genoa; and, conversely, L. salsoloides ascends to over 6,000ft. As to its hardiness, I am informed by one who grows it that it gives no more trouble than the well known L. narbonense. All these mountain flaxes belong to the southern ranges and are most abundant on the southern frontages of the hills. To be safe they should be grown in sunny sheltered spots in light limy soil. There is a dwarf, shorter-leaved variety of austriacum called collinum, which is found, rarely, on a few hills in Greece, and which should be a prize for introduction, as it combines the compact habit of L. salsoloides nanum with the exquisite colour of L. austriacum. The dwarf salsoloides is reputed the loveliest of the flaxes, yet I have so far noted it in one catalogue only, and even there it is not the dwarf form that is specified. The colour is white, flushed with rose at the base, and striated with rose on the petals. It has the rounded petals and broader sepals of L. alpinum and is a variety of the Spanish species L. suffruticosum, and not, as Farrer stated, of L. tenuifolium. L. suffruticosum is sub-shrubby (as is salsoloides), has white petals (sometimes ochre yellow), rarely washed with rose and never with deeper striations, and is a taller plant, always downy, with larger and more numerous flowers. I do not think it is in cultivation. I have not as yet confirmation that L. salsoloides nanum remains dwarf in gardens, and it is not without significance that Burnat does not mention this form. Its merits have been loudly trumpeted, and as the spindly habit of the linums makes them rather untidy, especially in wet weather, dwarfness in this family becomes an asset; and this asset, together with the brilliancy of its colour, demand for L. austriacum—especially if its variety collinum might be procured — more attention than it has received.—E. E. T.

A USEFUL BOOK.

THERE are few branches of natural history or science with such a full technical vocabulary as botany and the science of plants. It is bad enough dealing with our own tongue, but when these technicalities occur in foreign languages in different forms, the amateur's difficulty of making out the meaning is magnified a hundred times. This is obviously one of the main causes against closer international relations between horticulturists. In 1920 two Americans called Artschwager and Smiley produced an invaluable little volume called "The Dictionary of Botanical Equivalents," consisting of a compilation of French and German botanical terms, with their English translations. So successful has this been that the publishers have lately produced an enlarged edition, including in it Dutch and Italian botanical terms and their English equivalents, as well as the original French and German sections. This opens out a new field of literature to British gardeners, to whom most foreign horticultural writing has been a closed book. The book is published by The Williams and Wilkins Company of Baltimore, and is sold in the British Isles at 16s. 6d.

PYRUS IN SCOTLAND.

PYRUS SARGENTI.—This is a shrub of bushy habit with me about 5ft. high. Leaves, oval, 2ins. to 3ins. long, 1in. to 2ins. wide. Flowers white, produced in clusters of five or six on a stalk 1in. to 1½ins. long, followed by bright red fruit. This pyrus is a pretty plant when in flower and fruit, and is quite distinct among crabs by its bushy habit, and I can recommend it for a garden in Perthshire, where it comes into bloom in early June.

A FINE BUSH OF PYRUS SARGENTI.

PYRUS VILMORINIANA.—This small tree with me is about 8ft. high, a slow grower, and is one of the smallest in the mountain ash group, with neat, handsomely divided leaves. Flowers white, produced in June on slender stalked corymbs forming a pretty inflorescence 3ins. to 4ins. across. The fruit of this species is very attractive. The abundant clusters of white fruit with a slight pink tinge show up well in autumn. This species is a native of western China, originally reared in France in 1889, and is quite hardy, and one of the most elegant species introduced in recent years.—ANDREW HARLEY, *Glendevon*.

PYRUS VILMORINIANA IN PERTHSHIRE.

THE MOLY AND ST. JOHN'S WORT.

DODOENS, who lived towards the latter half of the sixteenth century, writes of the moly, and says that Dioscorides describes it as having leaves like grass, which spread on the ground. The flowers are white, so is the stalk, at the top of which groweth "a certaine thing fashioned like garlicke." The root, he goes on, is "rounde as an onyon." Then Pliny is quoted, but his moly has not a bulbous root; he agrees, however, with Dioscorides as to leaves, which he also compares to "grasse layd flat upon the ground." He also crowns the stalk with a white flower. Its properties are magical, in fact, there is almost no bad luck that it cannot ward off. Homer describes it and tells how Ulysses walked under its protection, unharmed in the sties of Circe. Milton alludes to the incident in "Comus," "That Moly, that Hermes once to wise Ulysses gave."

In Thomas Green's "Universal Herbal," date 1820, we find Allium magicum or Homer's Moly, described as having yellow flowers, and we are told that people grew it in their gardens, although it has a strong scent. So moly is an allium; and as the alliums are, bluntly speaking, onions, we gather that it has great counterbalancing qualities. Well, here they are taken from a later author, Alphonse Harr, botanist and poet. He says you may spill salt, meet a spider, a hare may run across your path, a crow may fly past on your left hand, you may sit down thirteen at dinner, you may do anything on a Friday that you like, and snap your fingers—if you have Allium aureum in your garden. You notice that it is aureum in this whimsical French author's fantasy. He describes it as having yellow flowers. He goes on to say that many people have it in their gardens, and, not being florists, know not that they

Digitized by Google

have it. They have astounding good fortune, everything prospers that they undertake, and they have absolutely no idea that it is to this assiduous vegetable that they owe all their immunity from evil. As soon as the lotus eaters are "propt" by Tennyson on "Amaranth and Moly," they become tranquil and contented.

There seem to be a good many molys: I find Homer's, Indian, Spanish Purple, Spanish Silver-capped, Yellow, Hungarian and Serpent's Moly.

Then, lastly, I look up moly in Chambers' English Dictionary. Alas, it is summarily dismissed as a "fabulous plant," a mere Mrs. Harris among vegetables, and I had hoped to plant it in my garden and to dwell under its ægis for the rest of my natural life.

The St. John's Wort is no less efficacious in succouring distressed humanity than the classic moly. St. John the Baptist is the saint after whom the Hypericum family is named. The longest day is dedicated to him, and on its eve all spirits of evil roamed abroad. Bonfires were lit, and dried herbs cast into the flames, St. John's Wort being an important one, and the fumes arising therefrom protected people from malign influences. After the date of John the Baptist's "decollation," a species exudes red juice in memory of his bloody death. The perforated St. John's Wort has semi-transparent spots pricked through the leaves, and could cure any wound in the "old unhappy times," and if it was more convenient to salve the weapon, withdrawn from the wound, rather than the patient, the result was quite as satisfactory. The Lady of Branksome made a wonderful cure of Deloraine by this method, compared to which prescribing by wireless is rather commonplace. If folk had St. John's Wort within reach, they could, like Ajax, defy the lightning. One species is called Tutsan, from the French *tout sain*. Fairies could not carry off a child and substitute a changeling if a bunch of St. John's Wort were tied to the cradle. Witches were robbed by it of their powers. Meg Merrilies' rhyme occurs to the mind:

"Trefoil, vervain, John's Wort, dill,
Hinders witches of their will."

It, being dedicated to Saint John, was a favourite plant of St. Columba. Finding a little child weeping for fear that some of the cattle committed to his charge should stray while he slept, St. Columba placed a sprig under the boy's arm, assuring him that the cattle would now be safe. It is, therefore, sometimes called by the curious name of "The little armpit of Columba." The trailing St. John's Wort, an apparently delicate little species, which the writer has in the garden, has really an iron constitution, and can oust many more robust-looking plants. It has been ungallantly named "The Lady's Tongue," as it runs on and knows not when to stop. Such are the qualities accredited to moly and the St. John's Wort, not much more wonderful, perhaps, than the real qualities possessed by many plants used in medicine. I shall end with a quotation from Lord Lytton. If a stranger had told a tribe of savages "that the herbs which, every day, they trampled under foot, were endowed with the most potent virtues . . . that tears and laughter, vigour and disease, madness and reason, wakefulness and sleep, were coiled up in these unregarded leaves, would they not have held him a sorcerer or a liar? The moly of the ancients is not all a fable."—E. M. J.

A GARDEN IN NEW ZEALAND.

THE part of my garden shown in the illustrations is an old creek bed, originally very rough, worn into deep holes and steep banks by the rush of storm water from the surrounding hills; the storm water we carried off with large pipes, levelled and filled most of the holes, and with the help of an artesian well, converted some of the holes into lily ponds. It has proved an ideal place for Japanese irises, as well as those of the ochroleuca and sibirica types, primulas of the moisture-loving kind, many of our native plants and trees that like partial shade and moisture, as well as such things as clivias and crinums.

The tree ferns in one illustration are Cyathea dealbata, the silver tree fern, very dainty when a little breeze shows the silver undersurface of the fronds. In the right-hand corner is a young rimu (Dacrydium cupressinum), one of our most beautiful forest trees in its early stages and also one of the most valuable commercially when mature; this tree is about 14ft. high and twenty years old. Immediately behind it is a pohutukawa (Metrosideros tomentosa), the Christmas-tree of New Zealand. In December it is covered with crimson heads of myrtle-like blossoms. The bamboo is a fine-leaved one we call "gracilis," and the tree on the left is a native matipo (Myrsine Urvillii) with reddish brown leaves curled at the edges, very distinct.

The tree in the centre of the other illustration is a native ngaio (Myoporum lœum), which, like the pohutukawa, grows right on the sea beach and is a valuable shelter tree on that account. This tree is covered with a climbing rose, Stella Alister Grey, which a fortnight later was crowned with its yellow clusters, which perfumed the garden. On the right, a liquidambar and a philadelphus, neither yet in full leaf. Behind, a flowering cherry, and, on the extreme left, a karaka (Corynocarpus lævigata), a glossy-leaved native tree with clusters of orange red berries 1in. in length. The iris is dalmatica, very effective with its grey-green leaves and soft blue flowers. The shrub behind the iris is rather an interesting native called koromike, or wine berry, (Aristotelia racemosa). It has large soft

A CORNER OF A NEW ZEALAND GARDEN.

SUB-TROPICAL GARDENING IN NEW ZEALAND.

Digitized by Google

leaves, purple underneath, and in spring is covered with tiny flowers of many shades of red, followed by red berries which change to black when ripe. It is very common, coming up as second growth when the bush is cut down.—J. GIBBONS, *Wanganui, N.Z.*

ROSE ALBERIC BARBIER.

THE value of the climbing rose for covering pillars or structures, and so producing beautiful effects when in flower, is well known. Some varieties of this section fulfil the purpose better than others, but each has its quota of beauty and charm for any garden, be it small or big. Not so frequently seen is the variety under notice, Alberic Barbier, and of which it has not been my good fortune hitherto to have seen a better specimen. This rose is early-flowering—at its best by mid-June—and bears white blossoms of semi-double form.

Incidental to the plant shown, I understand it is never pruned beyond the removal of dead wood, all new growths being secured in one or other direction for extension. The plant is in the garden of Miss Newman, Church Street, Ampthill.—C. TURNER.

A VERY FINE SPECIMEN OF ROSE ALBERIC BARBIER.

OMPHALODES LUCILIÆ.

NOMINALLY not difficult to cultivate if certain requirements or conditions are fulfilled, Omphalodes Luciliæ has a not undeserved reputation of being difficult to grow. Yet one sees it under conditions which do not always meet the injunctions of the experts, and I was much interested to see it growing and flowering admirably in a moraine in the rock garden in the nurseries of Messrs. Oliver and Hunter at Moniaive, Dumfriesshire. There it was evidently happy in a part of the moraine shaded by other plants in the rock garden close to the moraine. Some of these were really overhanging the omphalodes. The late Mr. Reginald Farrer, an enthusiastic admirer of O. Luciliæ, and probably the pioneer among British growers of moraine treatment for troublesome plants, advocated the moraine or a sunny wall or rockwork for O. Luciliæ. He laid great stress upon a free, open soil, with grit and lime rubbish, but while he gave such alternative suggestions he stoutly urged sunshine as an essential element. At Moniaive, however, O. Luciliæ was thoroughly happy and flowering freely and taking possession of the part of the moraine about it. When it is happy O. Luciliæ is indeed a lovely thing with its glaucous blue-green foliage and its fine, loose sprays of pearly blue flowers in great plenty, and is charming in its way. Its great enemy is the slug and happy are those whose gardens are not subject to the incursions of this terror of the grower of good and exquisite plants such as O. Luciliæ. Even the stony surface of the moraine is not always a sufficient barrier to protect this gem from this foe, and we must have recourse to all kinds of traps. Its undoubted beauty and elusive charm well repay one for any care and thought given in its successful cultivation.—S. ARNOTT.

EARLY VEGETABLES

BY EDWIN BECKETT.

(Concluded from page 556.)

IT was shown in the previous article how much can be done during the period of late autumn, winter and the spring, in this endeavour to obtain early vegetables, and as it may be of further assistance to those who would undertake this work, I will briefly tabulate the foregoing in two ways, the first being a comprehensive list under the months, and the second arranging the work according to the apparatus at command.

SEPTEMBER.

Cauliflowers.—Second week sow in cold frames for wintering, and repeat at end of month.

Endive.—Prick out into cold frames for wintering.

Lettuce.—Treat in same way as endive.

Mushrooms.—Make up fresh beds for succession.

Parsley.—Sow in cold frames for winter use.

Tomatoes.—Sow in heat for early spring work.

OCTOBER.

Cauliflowers.—Prick out seedlings from previous month's sowing.

Lettuce and endive.—Prick out previous sowings in cold frames, and lift plants from open ground, packing in cold frames for wintering.

Mushrooms.—Repeat as for previous month.

Chicory and rhubarb.—Place roots in mushroom house or cellar as noted for early supplies.

NOVEMBER.

Mushrooms, chicory and rhubarb.—As previous month.

French beans.—Sow in pots and raise in gentle heat.

Mustard and cress.—Frequent sowings for maintaining supply.

Seakale.—Lift plants from open, plant in mushroom house or in pots, and keep in the dark.

DECEMBER.

Mushrooms, rhubarb, chicory and seakale.—As for previous month.

Asparagus.—Commence forcing in frames on hot beds.

JANUARY.

Cauliflowers.—Sow in boxes or in a frame on mild hot bed.

Lettuce.—Raise as noted for cauliflowers this month.

Mushrooms, rhubarb, chicory, mustard and cress, and seakale.—As noted for previous months.

Carrots.—Sow stump-rooted varieties during first week in frames on mild hot bed, and long varieties in heated brick pits in good depth of suitable compost.

Broad beans.—Sow in large pots or boxes, in cool vinery.

Onions.—Sow in boxes and raise in heat for planting out.

Peas.—Early varieties sown in pots and raise in cool house.

Potatoes.—Plant sets in large pots or boxes and place in a cool vinery.

Radishes.—Sow between the rows of carrots, in frames and pits.

Asparagus.—Continue forcing as noted for previous month.

FEBRUARY.

Chicory, rhubarb, mustard and cress, and asparagus.—Repeat as above noted.

Tomatoes.—Make sowing for main crops and raise in heat.

Broad beans.—Sow in cold frames (in boxes) for early planting.

Peas.—Raise in boxes in cold frames for early planting.

Potatoes.—Plant sets in frames on mild hot bed.

Vegetable marrows.—Raised in heat for pot or frame on hot bed planting.

Celery.—Sow seed for early crops and raise in moderate heat about the middle of month.

Turnips.—Sow in cold frames about mid-month for early supply.

MARCH.

Rhubarb, asparagus and mushrooms.—As for previous months.

Lettuce.—Sow in boxes in cold frames for planting out.

Broad beans.—Final sowing as noted for February.

Peas.—Sow marrowfats, for early planting, in boxes and raise in cold frames.

Potatoes.—Another planting may be made in frames if room.

Beet, globe.—Make a sowing in frames on mild hot bed.

Brussels sprouts.—Where early buttons are wanted a sowing should be made in boxes and raised in a cold frame.

Mint and tarragon.—These can be brought into early use if planted in boxes and brought along in frames on mild hot bed.

The foregoing monthly work, for the six months of the winter period, can now be further summarised as follows:

COLD FRAMES.

Cauliflowers.—Two sowings at middle and end of September and prick out in October, into other frames.

Endive.—Prick out August sowings into frames in September, and again in October, and

Digitized by Google

lift from open ground in October, packing in frames for wintering.

Lettuce.—Deal with on the lines noted for endive. Make a sowing in boxes in March for planting out.

Parsley.—Sow in September for winter use, and prick out in October.

Broad beans.—Sow in boxes in February and March for planting out.

Peas.—Sow in boxes during February and March as detailed above.

Radishes.—Sow between potatoes grown in frames in March.

Turnips for early supplies may be sown about the middle of February.

Brussels sprouts.—To get early buttons a sowing may be made in boxes in March, and raised in cold frame.

HOT BEDS.

Asparagus.—Forcing of this can be commenced in December, and continued on through January, February and March.

Cauliflowers.—Sow in boxes during January, and raise in frame on mild hot bed.

Lettuce.—Early supplies can be sown during January, either in boxes or direct into the frames.

Carrots, stump-rooted.—Sow first week in January.

Potatoes.—Set the "seed" in frames on mild hot bed in February.

Radishes.—Sow between the foregoing potatoes.

Beet, globe.—Sow in March in frames on mild hot bed.

Mint and tarragon.—Put in boxes and place in frames on hot bed in March.

Vegetable marrows.—Grow on in frames from plants raised in heat.

HOUSES AND PITS.

Tomatoes.—Sow in September for early spring work, and in February for main crop.

French beans.—Sow in 8in. pots in November, and raise in temperature of not more than 65°, and repeat sowing in January.

Carrots.—During first week in January, sow in brick pits, in good depth of compost.

Broad beans.—Sow in January in large pots or boxes, and raise in a cool vinery.

Onions.—Sow in boxes during January to obtain large specimens.

Peas.—Early varieties should be sown in large pots in January and raised in a cool house.

Potatoes.—Plant sets in large pots or boxes during January, and grow them in a cool vinery.

Radishes.—Intersow the rows of carrots in pits.

Celery.—Sow in middle of February in moderate heat.

MUSHROOM HOUSE OR CELLAR.

Mushrooms.—Make up fresh beds in mushroom house monthly during the winter period to maintain supplies.

Chicory.—Make a start in October, by taking a few roots into the house or cellar, for salading work, and continue with fresh supplies of roots about every three or four weeks.

Rhubarb.—Monthly supplies can be dealt with in a similar way to chicory, starting in October.

Seakale.—Making a start in November, this can be treated in similar fashion.

As was stated at the beginning of these notes, no attempt has been made to deal with every aspect of the subject. Cultural details have been, for the most part, omitted, such as instructions as to covering against frost, where necessary, airing, syringing, composts, temperatures (to the point of exactitude), etc. It would need a volume to set all these points out, and a careful grower will soon settle these for himself, but enough has been written to make the subject fairly comprehensive, and the writer's last wish is that many more will take interest in this fascinating and profitable side of vegeculture, to their own benefit and gain.

CORRESPONDENCE

COLOUR AND CATALOGUES.

SIR,—In an Editorial the other week you made the timely suggestion that the R.H.S. should publish a colour chart. This has already been done in France by the Society of French Chrysanthemum Growers, in collaboration with M. René Oberthur, in the form of a colour dictionary, under the title of "Répertoire des Couleurs," published in Paris in 1905. What has been done by a specialist society in France can surely be done by the premier horticultural society in the world. If issued under authoritative auspices, a colour dictionary would become an indispensable book of reference both to the horticultural and to other spheres of activity, and though expensive of production, it would have an almost guaranteed sale.

I write "expensive" advisedly, as a production of this kind must be the printer's very best work, otherwise the present confusion will become worse confounded. Mr. Farrer deplored, and rightly, the colour misfits which disfigure handbooks on alpine plants and which, in many cases, give a totally inaccurate idea of the flowers which they thus libel. Modern colour printing is put to shame by the colour work of a century ago, as witness the old plates in the Botanical Magazine. Let me hasten to add that the too few coloured covers issued by THE GARDEN do not come within this condemnation.

A glance through half a dozen garden catalogues will, I am sure, prove that colour is a weak point with their compilers. Thus, Ramondia pyrenaica is variously described as violet, purple or lilac; Cyclamen europæum as red, crimson or purple; Androsace lanuginosa, as rosy lilac, rose or bright rose; Primula marginata as bluish lilac, rosy purple or lavender; P. Bulleyana as apricot, orange or orange-scarlet; and P. Juliæ as claret-crimson, deep rose, rose-purple or bright violet. Examples might be multiplied. I am not scoffing at the catalogue writer; colour description is a matter of the utmost difficulty.

Not that I would have any attempt at standardisation of the descriptions of flowers, nor do I think a colour dictionary would have any such result. The shades and combinations of colours are so infinite, and a flower field rivals the artist's much-daubed palette rather than his colour-box.

An authoritative colour guide is all the more essential to-day by reason of the rapidity with which modern colour taste is changing, and the increasing elusiveness of the colours that leap into vogue. Not so long ago magenta was anathema. Nowadays it is popular, though it is not the simple magenta of old. It is a more complex colour, expressing itself in shades of cyclamen and fuchsia. The great Paris dressmakers are coining new colour terms with every autumn and spring season, and look how often they borrow from the garden: delphinium blue, parma, pervenche or periwinkle blue, hyacinth blue, beech, almond green, artichoke, Bois-de-rose, are all taken from this autumn's "Fashion" announcements. Modern tones such as nude, shrimp, sea blue, dust blue, lead pencil, bottle green, steel, Puritan grey, camel's hair, rubber, crayon pink, ibis pink, biscuit, lacquer red—taken from the same source—bear witness to the search for new shades and for new colour terms.

It may be said that these are fantastic names dictated by the passing phantasies of Fashion. Yet they do, in fact, suggest by association the refinements of colour which alone are now demanded. Nor is the garden catalogue so far behind. In one of his books Mr. Farrer resented the impossibility of describing the colour of a flower without reference to a precious stone. Thus we use ruby, coral, amethyst, pearl, turquoise, emerald, sapphire and garnet purple, and these seem pre-eminently suitable to the brilliant lights of the high alpines. But Mr. Farrer himself wrote of the "grey flannelette" of edelweiss, and thus borrowed from textiles; and my catalogue describes other flowers as "white felt," or "satin-white," or again, "purple-shot sapphire."

If every individual writer gives rein to his own exuberant fancy, we shall arrive at chaos—whence arises the need for co-ordination and direction. But for myself, many colour terms have within themselves a definite colour concept, which is arrived at on the principle of the association of ideas. A defect of the "Répertoire des Couleurs," which I mentioned above, is that it uses terms which, in this country at least, carry with them no colour associations and are machine-made and inexpressive. Among these are "Orient blue" and "Victoria blue," the latter being divided into four shades. What on the other hand could be better calculated to cause a clear colour concept to spring up in the mind than eggy, brick red, primrose, snow white, blush and so on—even though the yoke of an egg may be deep or anæmic, primroses may sometimes be white or red, the snow of the upper glaciers be of a purity not always known to the denizens of our smoky towns, and a maiden's blush (if such now there be), may vary from shell pink to vivid carmine? The editor has suggested "verna" or "acaulis" as colour terms, because "gentian-blue" is not stable. But neither, after all, is the colour of verna or acaulis stable. In addition, "acaulis" strikes me inevitably as machine-made, and evokes no colour association. Verna and acaulis are adjectives, meaning vernal and stemless respectively, and I would have difficulty in dissociating them from those and associating them with other interpretations. It occurs to me that all the new colour terms I have instanced are based upon nouns, not adjectives—or names of things which automatically evoke in the mind the desired colour. As colour terms they are new, but they are old, well known words. Gentian blue to my mind is quite definite, even though the colours of actual gentians do vary very greatly. What is stable is not the colour of the gentian, or of the brick, or of the blush, but the popular conception of gentian blue or brick colour or blush. Again, to describe a flower as "purple shot peacock; blue flamed orange" is bad enough, but I hesitate to suggest as a substitute a four-worded horror of plant names like verna or acaulis.

The real problem of colour description is not one of new colour terms, but of using with accuracy old, well known words to suggest refinements of shades which the old colour terms are too broad to convey. Hyphenated words like "rose-lilac" are objectionable, not because they are hyphenated, but because they are indecisive; the two colours, "rose" and "lilac" are not transmuted into one colour by the name "rose-lilac." Similarly "white-rose" would be useless, because it would not give rise to a definite conception, but the two colours "white" and "rose" have been transmuted, as in a crucible into the beautiful word "blush." It is a problem of accuracy of the adaptation of words to colour ideas, and of co-ordination by a central authority. Some people, as Mr. Farrer was, are gifted with an uncanny ability to make a living colour arise out of the written word; but the majority of us need a guide. It is in this respect, I submit, that a colour dictionary would render great service.—E. ENEVER TODD.

SWEET WILLIAMS AND NEPETAS.

SIR,—I was interested in the note on the propagation of sweet williams by cuttings, because I have always done it this way, thinking that it was quite a usual way of treating them. I always, however, transplant the cuttings early in the spring, when they are rooted, owing to the retentive nature of our soil. Old plants from which all the straggling shoots have been removed for cuttings, will shoot from the crown, to make fine, bushy plants for the next year.

As you said recently, nepetas are very easily increased by cuttings. Last autumn I had a few odd bits torn off a plant given me. One of these rooted well, and last July I took twenty-four cuttings from this one plant, all of which are nice, well rooted plants now. The effect of this robbing the plant early has been to make it flower on branch shoots all the more. There are plenty of shoots for cuttings which could be taken now.

The most effective planting of nepeta that I have ever seen was in a sunk garden. A long, low brick wall ran through it. All along the edge of this wall, a broad belt of nepeta was planted, which overhung the wall, and strayed here and there, back from it, on the top. The background was a well covered pergola. The effect was very fine. —J. E. P. BOOTH, *Surrey*.

THE DIVIDING OF MICHAELMAS DAISIES.

SIR,—Claremont's note on page 531, advocating the division of clumps every two years coupled with another season's experience in my own garden of planting single shoots annually, makes me wonder whether the one-stem system is as good as the other for practical flower-border purposes. It has two very valuable advantages, in that it gives us extra fine flowers and also because it enables us to give the go-by to that disfiguring disease which asters have to pay as a penalty for their increased popularity. On the other hand the joints which attach the large side shoots to the central stem seem to be peculiarly brittle. Not only are these side shoots broken off by high winds but, as I have noticed on two occasions this autumn, heavy and continuous rain has had precisely the same effect. I cannot think of any dodge of staking the plants which, without being too obtrusive, will give the necessary support to prevent these contretemps. Obviously a sheltered position is the first idea that comes into one's head. My collection this year is in such a position. It has, however, been a case of out of the frying pan into the fire, for avoiding the Charybdis of wind they have fallen foul of the Scylla of rain.

Although I fear the answer will be "no," I ask, is there any dodge whereby these pitfalls can be avoided?—JOSEPH JACOB.

ASTER THOMSONII NANA.

SIR,—I have been pleased to see so many references to this desirable plant in the horticultural Press lately.

Personally, I think its beauty and general utility cannot be exaggerated. Apart from its usefulness as an outdoor subject, it makes a delightful pot plant for conservatory work, and under these conditions it shows an even more beautiful shade of colour.

I have grown every variety of Aster Thomsonii I could secure, but the true nana variety is, in my opinion, the best.—T. L., *Newcastle-on-Tyne*.

CHEIRANTHUS HARPUR CREWE.

(C. ALPINUS FL. PL.)

SIR,—Your correspondent "W. F." in the issue of September 19th may rest assured that the above is still in cultivation.

It is worthy of much more general use. Apart from the hardiness of the plant and its gorgeous display of very sweetly scented flowers, it is an object of beauty when not in flower, much resembling a small neat plant of Veronica Traversii.

It roots easily from cuttings at almost any time of the year. As a pot plant for conservatory decoration a three or four year old plant is as attractive and fragrant a subject as could be desired.

Although it is many years since I first gave instructions for increasing the stock of this plant and I have periodically repeated the same, I do not appear to have any more than formerly.

Perhaps the explanation of this is due to my foreman's remark that "every customer wants it who sees it in flower."—T. A. LAWRENSON, *Gosforth, Northumberland*.

THE WILD TEAZLE.

SIR,—The remarks of W. Linders Lea in the issue of September 19th concerning dipsacuses greatly interested me, as I have grown them in my garden for many years, and have

A HANDSOME TEAZLE.

found them very ornamental, if somewhat of a nuisance when the seed is allowed to fall.

A few years ago some teazle seeds were collected in an out-of-the-way district among the Kentish Downs, because the heads themselves were of exceptional size, the stems being about 3ft. or 4ft. high. The seeds were sown, and the resulting plants produced similar large heads upon stems quite 6ft. in height.

Owing to alterations in the garden, the self-sown plants from these domesticated teazles were pulled up, and to all appearances the dipsacus was banished from the garden.

But this was not the case, for a plant was observed one day close to some palings that surrounded a kitchen garden, among some other tall subjects that were allowed to grow unmolested. The plant grew to a large size, with enormous leaves, and the final result was the splendid plant shown in the accompanying illustration, the topmost head being just 7ft. 3ins. from the ground level!

This proves the value of the wild dipsacuses when brought under cultivation. There was an abundance of decorative material of an everlasting nature provided by this one plant, which did not demand the least attention from the gardener nevertheless. Many a wild-looking spot in gardens or wasted ground near trees could be beautified by a plant or two of these wildings, and they effectively hide the ugliness of sheds or fences. —H. A. DAY.

ROSE GOLDEN EMBLEM.

SIR,—I am most interested by Mr. Easlea's letter in this week's number on the subject of Rose Golden Emblem, and, as a very enthusiastic amateur rose grower, I should like Mr. Easlea to give us more details as to the culture of this rose, as well as his own experiences with it. In my small garden I grow practically nothing but roses—over a thousand—and have been very perplexed at the way Golden Emblem is cut back in winter after pruning; it seems very susceptible to keen winds. My soil is well worked and well limed clay, and I have taken a good deal of trouble in preparing it. Those plants which have not been cut back by the weather have not made a normal growth, few of them being over 2ft. high, though they have produced a very fair amount of bloom. Personally, I find that Christine is a better grower in this soil, though the blooms are not quite so large as those of Golden Emblem. Another famous rose, with which I have not had much success is Los Angeles. Last year, its first season with me, it did quite well, in spite of the weather; this year it has been very poor, producing few blooms and still fewer leaves, though at the same time showing no apparent signs of disease. I cannot account for this, as it is in a good and sheltered position, and there are at least sixty plants in the one bed, all of which show the same signs of poorness of growth.

On the other hand, I have been very successful with Betty Uprichard, which I consider to be one of the finest bedding roses in cultivation, and also with General McArthur, Hoosier Beauty, Independence Day, Lady Pirrie and Mme. Edouard Herriot. As a mere amateur with only a few years' experience, I am rather at a loss to explain my lack of success with two such popular roses as Golden Emblem and Los Angeles, and I should welcome the advice and opinion of expert rosarians, like Mr. Easlea, on the subject. I should like to add that I have heard this year of several other people besides myself who have been unable to grow Golden Emblem successfully. —W. R. YOUNGER.

OUTDOOR SEED BEDS.

SIR,—I have been much interested in your leader in THE GARDEN for September 19th *re* Outside Seed Beds. I have been trying a similar plan, but with commoner things, preparatory to sowing rarer seeds when I have sufficient stocks; but the trouble I have experienced has been with worms: they either expose the seeds with their casts, or raise the tiny seedlings out of the ground. Have you experienced any trouble in this direction, and, if so, how have you surmounted it?—E. B. ANDERSON, *Devon*.

[*Strangely enough, I have not been troubled with worm casts, which is, perhaps, due to the fact that the particular spot in which the seed beds were made had been undisturbed for many years.*—ED.]

PLEASE REMEMBER TO TELL OTHERS ABOUT YOUR PLANTS THROUGH THE COLUMNS OF "THE GARDEN."

SOME UNUSUAL TREES FOR AUTUMN PLANTING

THE planting season being once more upon us, land and garden owners have again an opportunity of acquiring new and interesting treasures.

A summer spent in horticultural study in Brittany has revealed to me the fact that several trees which are very common in that land of grey skies and much rain are rarely to be found in Britain, the climate of whose southern and western counties much resembles that of Armorica.

Every garden of any size in Brittany possesses at least two Acacia Mimosa trees—one of the feathery-leaved variety—the sprays of which are sold in such quantities in the spring—and the other the narrow, flat leaved variety.

The former grows as large as an ash tree and has a wide-spreading habit. It is a mass of yellow blossom in the spring, being as floriferous as its brethren of the same variety which grow along the side of the Nile and afford such welcome shelter from the blazing Egyptian sun.

The Bretons subject the feathery acacia to very drastic thinning, as, if left to its own devices, it quickly grows beyond all bounds. It is frequently trained to cover the walls of houses and gardens. This it does with amazing rapidity. Great sprays are culled for house decoration with great advantage to the tree.

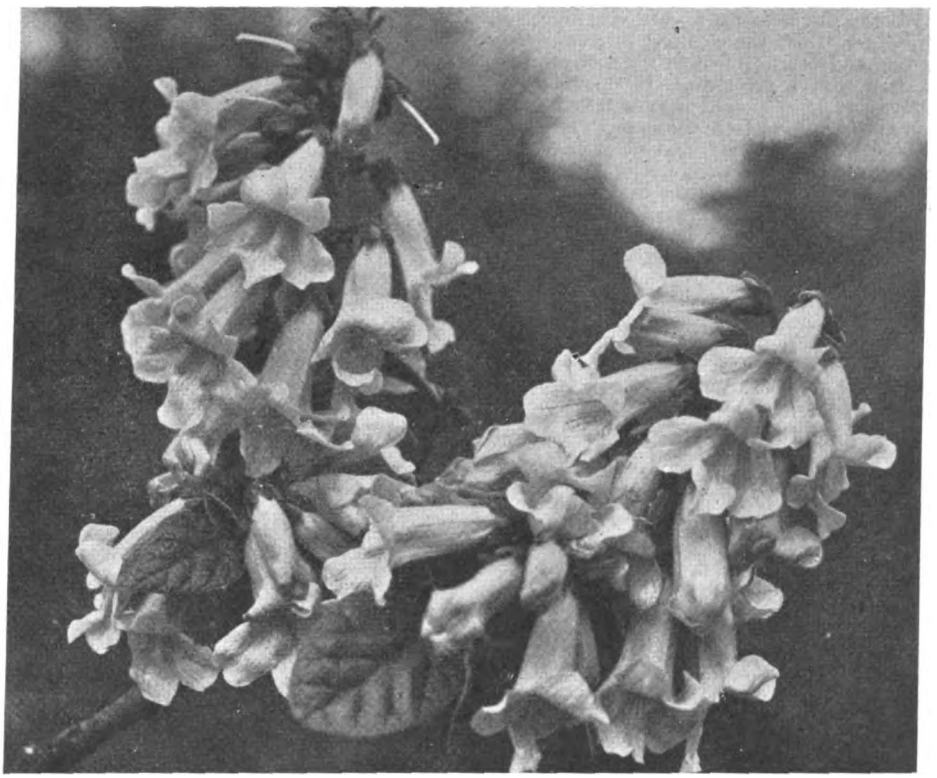
In September and October the flat-leaved Acacia Mimosa lights up the dull days with its large clusters of flowers, the colour of newly hatched white ducklings. Neither of these acacias is given any special care, and no protection is afforded them in winter.

Eucalyptus trees are also ubiquitous in Brittany, where they grow as high as Lombardy poplars. They are constantly lopped and the side branches are thinned out yearly, not only to keep them in bounds, but also to ensure a plentiful supply of the young shoots whose delightfully soft colouring renders them invaluable for picking.

Petticoat and other greenhouse varieties of fuchsia grow as large as laurel bushes in Brittany. A cottage where I lodged has a fuchsia tree of a very large-flowered variety which was planted as a cutting over twenty years ago. It reaches to the roof and completely covers one half of the house. On one side it grows out from the wall and forms a shrub-like growth, its top there being trained to extend outwards and form a bower over a path. It is covered with flowers from May to November, and is clipped severely all over every year—otherwise, its owner says, "there would be room for nothing else." Beyond giving it an occasional tilth and a little manure once a year, no care is taken of this fuchsia.

In the same garden are pentstemons growing as large as rhododendrons, which have been left in the same spot for many years. They have very large, deep red flowers, and are cut to the ground every autumn, but are given no protection in the winter.

The false acacia tree (Robinia Pseud-acacia) grows exceedingly well in southern England, but is, nevertheless, by no means common there. It will stand a vigorous climate, as in north-eastern France, where the winters are Arctic-like and long, false acacia trees are very abundant and attain to a great size. In fact, these trees will grow almost anywhere and in any soil, though they particularly delight in a heavy clay.



THE BLOOMS OF PAULOWNIA IMPERIALIS.

I have seen magnificent ones growing in almost pure chalk in the Marne Department. The robinia flowers early in the spring, and its deliciously scented blossoms are much beloved by bees. The shell-pink flowered variety is seldom seen in Britain, but it ought to be extensively grown on account of its exquisite beauty, which is arresting. I first saw it at Chalons-sur-Marne, where about half a dozen large, finely grown trees are planted in a group opposite the Prefecture. They were so lovely that I found it hard to take my eyes off them.

Catalpa trees, too, are rarities with us, but there is no reason why they should be, as they are not at all "miffy." Few trees surpass them in beauty. In Paris they line avenues and enrich the public gardens, but for the perfect contemplation of their beauty of form and the loveliness of their May flowers, catalpa trees should be planted in solitary splendour on a large lawn or in a park.

Paulownia imperialis is another attractive but little-known tree which flourishes in any aspect and most soils, though it prefers a chalky marl. It is an ideal tree for parks, as it has a magnificently spreading habit, and its large, light green leaves and bunches of white flowers with red stamens, which appear in July, render it highly ornamental in such situations.

VICTORIA SLADE.

GARDEN TECHNIQUE

Notes on the Technical Side of the Garden and the Cultivation of Plants.

CALCEOLARIAS AND CUTTINGS OF BEDDING-OUT PLANTS.

THE calceolaria is grown very extensively in many gardens, and especially in villa and suburban gardens, by those residents who understand the plant. But some who like this flower fail to grow it satisfactorily, and lose many plants early in the summer. The writer often lost many before he adopted the following plan: In October the nice fresh basal shoots were selected as cuttings and duly inserted 2ins. apart in a firm bed of sand in a cold frame and watered. Then the frame was closed for a fortnight and shaded from any bright sunshine; afterwards a little air was admitted night and day, except in frosty weather. Probably the cuttings were sometimes frozen, but to prevent loss the frame was kept covered till the thaw was complete. Early in February roots began to grow, and so more water was applied and air admitted. At the end of March the young plants were transplanted in a bed of loam in another frame and fully exposed after the first ten days there. At the end of April they were planted in the flower garden. Rarely did any die; they formed big, bushy plants and were more satisfactory than any planted at the usual time in June. A few kinds of cuttings, such as those of heliotrope, verbena, alternanthera, coleus, iresine, etc., should be kept growing all through the winter in a warm greenhouse temperature; but those of zonal pelargoniums are best kept in a cooler temperature on shelves in a greenhouse or glass-pit, where fire-heat is only used at night and during foggy and frosty weather.

Digitized by Google

A callus only is formed in the autumn, so small quantities of water should be applied. —GEORGE GARNER.

ROOT-PRUNING FRUIT TREES.

IN certain soils fruit trees make roots very freely, especially in loose ground. The annual shoots are strong—woody, too thick, and not well matured, bearing plump prominent eyes or buds; and, instead of a rich harvest of fruits the next year more and stronger wood results. Now, if we, every year, cut away this top growth without also cutting back some of the long, fibreless roots, the tree will not for many years come to a fruit-bearing state. The inexperienced cultivator may tell when a tree needs root-pruning as well as branch-pruning if he observes the annual growth closely. It should be moderate in strength, thinly disposed and well ripened by the time that the leaves fall naturally. This refers mainly to apple and pear trees. A newly planted tree receives a check and this check prevents the new growths from becoming, for at least two years, very luxuriant. If, after this time, they become very strong and unfruitful, then try root-pruning. A tree with a stem 3ins. in diameter 1ft. above soil level should have a trench taken out 2ft. 6ins. away from the stem. The trench should be 16ins. wide, and deep enough to expose all roots crossing; cut off the long fibreless roots and refill the trench with good loam, making it very firm. Larger trees will require that the trench be made at a greater distance. Wall trees, those grown as espaliers, bushes as well as standards, may all be treated in this way. It is very essential to success that the ground be fairly dry when the work is done, especially when refilling the trench.

HOUSING POT AND LIFTED PLANTS.

THERE are several kinds of plants grown in pots throughout the summer months on beds of ashes, outside, then taken into the greenhouse or conservatory to flower there in the dull days of winter. There are some, too, planted out in the summer and lifted in the autumn, potted or planted in beds under glass. Now, although some of these plants are regarded as fill-gaps, they are all useful and, if properly treated, very beautiful, and have been grown without causing much trouble to the cultivator. Salvias are generally grown outside or in cold frames, mostly exposed to the weather, and when they are placed under glass frequently shed their basal leaves and flower buds. The sudden change causes this check. These plants need air, but cold draughts are fatal to them. Extra care should be taken in the matters of ventilation and watering. Really, all plants so housed require this special attention. As the pots are closer together and the season is winter, less water is required—only sufficient to maintain the freshness of the leaves and flowers. Plants lifted from the open border and replanted in borders under glass should be watered thoroughly when first planted, then syringed lightly in bright weather early in the day, in preference to much watering at the roots. The structure should be closed, too, for a week, and afterwards more air should be admitted as the plants make new roots. The same treatment is advisable in the case of plants lifted and potted.

PEAS AND BEANS FOR AUTUMN SOWING.

EARLY and late supplies of both broad beans and peas are always appreciated, and to secure an early crop a sowing of both should be made about three weeks hence. In the meantime, the ground can be prepared. It should be dug deeply, and, if the soil is in good fettle, no manure need be given. For peas select the warmest and most sheltered spot in the garden and, if possible, a border sloping to the south; while in a few gardens will be found a border immediately in front of some greenhouses, which is ideal for early crops. Sow the seeds in flat drills, and at this season it is advisable to sow fairly thickly, as the weather and slugs will account for a number of the seedlings. To ward off the attacks of mice the seeds should be damped with water and then sprinkled with red lead. Any of the round-seeded varieties of peas are suitable, but so far I have not found one to beat The Pilot, which attains a height of 4ft. to 5ft. and produces a good crop of well filled pods.

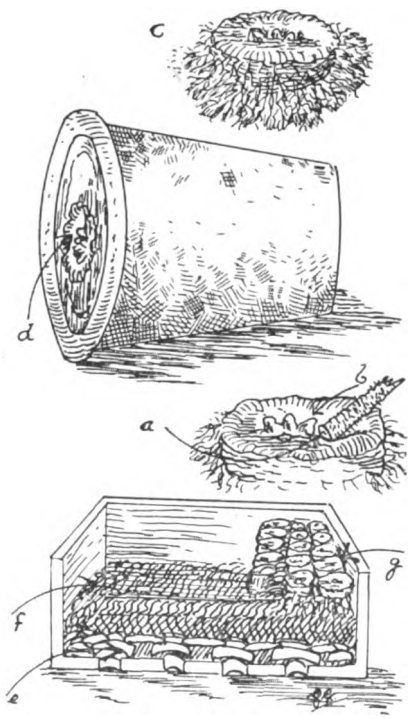
Broad beans do not require such a warm position, but it is best to choose a piece of ground sheltered from the cutting east winds, which often play havoc with the young plants during the early part of the New Year. The seeds should be planted in lines 18ins. apart and about a foot allowed between the seeds.

Just as the seedlings appear, a sprinkling of soot or air-slaked lime will help to keep off slugs and snails.

An excellent variety for autumn planting is Exhibition Longpod, but all the Longpod type are suitable.—T. W. B.

PREPARING AND WINTERING FLOWER CORMS AND TUBERS.

THE true lover of flowers has an equal affection for the dried corms and tubers when the season of rest for the latter comes.



The careless or indifferent cultivator neglects them, perhaps quite unintentionally, and does not realise the harm that has resulted till he takes out the various stocks and finds many rotted. The achimenes, those lovely little flowers so well adapted for pot and basket culture, can be wintered quite easily if the ripened tops are cut off 1in. above the soil and the latter, containing the corms, is left undisturbed till early next spring, being kept dry in the meantime. Pots of tuberous begonias and gloxinias are often placed one on the top of another under a greenhouse stage, and thus many unripe stems are violently broken off. Gladioli corms are lifted and the tops cut off while the stems are green and sappy. It is time enough to lift these in mid-October; then the corms with stems attached should be laid in boxes in a cool shed and left there till all life is gone from the stem and, in due course, it will be possible to store the ripe, polished tubers or corms in paper bags. Gloxinias and tubers of begonias should not be wintered too near to hot-water pipes, and there should always be boards between and the space filled with leaf-soil, peat or hemp seed. The crown of a corm is shown at *a* and *b*, with the ripe stem falling naturally away; the corm, *c*, is now fit to store in boxes, or, as at *d*, in pots. At *e* the drainage—old—is shown; the dry soil at *f* and the corms packed close together in dry material at *g*.

UNSATISFIED PLANTS.

MOST gardeners, at one time or another, are confronted by plants or shrubs which, no matter how carefully they may have been put in and tended, decline to prosper. Patience must, of course, be exercised in any case, and I generally give a plant two full growing seasons before deciding whether it is going to do satisfactorily or otherwise. But patience is a virtue in which one may indulge too freely and a too complacent attitude may mean the loss of years in so far as the flowering of some plants is concerned.

In endeavouring to discover the reason why a plant stubbornly refuses to respond to the treatment accorded it, one must review a number of possibilities. Primarily, there are the nature of the soil, feeding and aspect, but, important as these may be, they are not everything. There is atmospheric humidity which may vary considerably within the limits of quite a small garden. Some plants will thrive in the shade of a rock and detest the shade of a bush, even if not actually overhung by it, and there are many which will thrive in congenial company and decline to do otherwise than languish when lonely. Soils, again, which may often seem exactly alike in this border and that, may obviously be very different in the plant's opinion, and the same remark applies to aspect.

For some years we have been accumulating practical evidence that in most instances in which plants decline to be agreeable it pays one to take the bull by the horns and give the object a fresh start in a new position. This in the absence of any definite knowledge as to the cause of the plant's failure in the old spot, and without any assurance that it will do any better in the new, may be an empirical form of procedure, as well as an acknowledgment of defeat. Even so, the best of us still have so much to learn, especially about many of the newer subjects, that the practice of trying it on the dog is likely to be popular for a long while.

By way of an example, to illustrate the salutary effect of a shift upon an unresponsive subject, I may record the instance of a bush of Buddleia alternifolia, planted against a west wall, which did not grow more than about 6ins. in as many years. It was ever a feeble, disgruntled creature in spite of all possible attention. Last winter this specimen was lifted and again placed against a west wall in another part of the garden, the soil to all appearance being much like that of the old site. The result of this move was an immediate response on the part of the plant. It flowered, sparsely, it is true, at the normal time and made such extraordinary growth that it has leaped from a miserly shrub of 2ft. to one of extraordinary health and robustness, its longest growths now measuring no less than 8ft.

A very similar experience to the above we have had with a rare form of Ceanothus papillosus. This made at most but an inch or two of new wood annually for some ten years, and some of that often died off in places. At length we decided to risk shifting the precious object, and it has shown its gratification for the change by growing more

Digitized by Google

in a single season than it had previously achieved in a decade. A yellow Banksian rose was given one of the choicest places in the garden, one that seemed eminently suitable, yet it declined to move, taking not the slightest notice of our ministrations. This shrub was at length moved to another spot, which anyone might consider identical as regards conditions with the other. But the rose thought otherwise, for it made several 5ft. growths the first season.

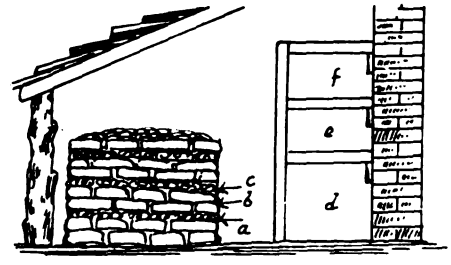
A like story might be told of Berberidopsis corallina, Clematis Armandi, an abutilon, a stuartia and several other shrubs, all of which are now prospering abundantly in new homes after having been tried in various spots without success. As for rock plants and herbaceous subjects, one has in these an even greater scope for the exercising of a little more of what one may term tolerance towards a plant's susceptibilities. That you can carry this sort of thing too far I readily admit, and the fidget who is for ever moving his plants from place to place is not likely to achieve much satisfaction. My object here is merely to suggest that the gardener who tells you a certain plant will not do in his garden might have reason to alter his opinion were he to try the subject in another site. The very act of lifting and replanting may in itself do good, as in the case of a specimen put out from a pot and whose roots have continued to go round and round, winding themselves into a ball. We are all, more or less, experimentalists and none can say why Daphne Cneorum ramps in my soil and utterly refuses to exist in my neighbour's. Nor can one explain why the latter grows Viola bosniaca like a weed, while with me it is a hopeless failure. And, after all, if we were able to give a reason for these problems, if gardening became an exact science and we believed half the things the catalogues and books tell us, our work and pleasure would lose most of their zest.—A. T. J., *N. Wales.*

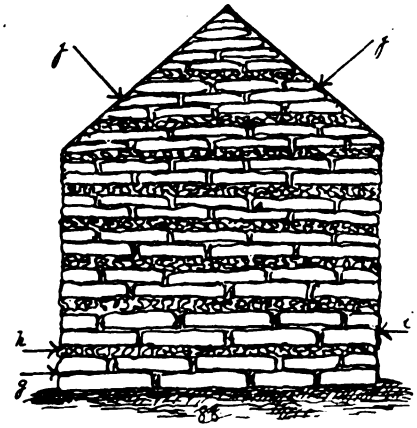
PLANTING BULBS IN BORDERS.

WHERE the flower-beds are occupied by summer-flowering subjects the latter must be removed and the soil duly prepared before any bulbs can be satisfactorily planted in the same borders. But all necessary work should be forwarded as much as possible in readiness for the planting of the bulbs in due time. Of course, bulbs thrive best in an open, well drained soil. All cultivators do not possess such and, therefore, unkindly soils should be improved by thorough pulverisation and the addition of some lighter material, such as gritty soil and leaf-mould. Many bulbs may be entirely grown in pure well rotted leaf-soil without the addition of any other rooting compost, so in tiny town gardens a bag of leaf-soil and some sand would be sufficient to form a little bed wherein to grow tulips, hyacinths, narcissi, snowdrops, or scillas, crocuses, etc. If such composts as leaf-soil and old potting soils are mixed with the ordinary garden loam it is advisable to take out as much of the latter so that the normal level of the border be maintained. Furthermore, I like to remove the top 4in. of soil from each bed, to add the rotted manure and thoroughly mix it with the lower layer of soil when that is deeply dug. The surface soil first removed should then be replaced and the bulbs planted. If the bulbs are planted before groundwork plants, such as aubrietias, every bulb should be marked so that other subjects be not planted directly over them.—G.

PROCURING AND STACKING POTTING TURVES AND OTHER INGREDIENTS.

AS millions of plants are grown in pots every year and also in borders in our glass structures, we are obliged to provide a suitable material for them to thrive in. The principal ingredient, generally, of all our composts is turfy loam. This should be cut and stacked at least four months before it is required for use. If used earlier, the grass roots are not dead and, of course, they begin to grow again in favourable conditions and give trouble. For this reason, chiefly, we should begin to cut and stack our supplies of turves in October. If I had the opportunity to choose, I would prefer a good fibrous, yellow, turfy loam from an upland; but we are not always able to procure such. For several years I had to cut turves from a low-lying meadow where they were soaked with water during a great part of the year, and were, consequently, in a sour state. To sweeten them I added lime and old lime rubble to the heap. To improve matters, in spring such turf should be opened out and restacked. An open shed is very useful. In such, stack the turves near the front as shown. On the two first layers place some rotted manure, *a*, then more turves and manure as shown at *b* and *c*. At the back of the shed, on the ground, *d*, place peat and leaf-soil supplies,





and above, at *e* and *f*, manures in bags or boxes and tins, also stakes and labels. If turves are stacked in the open, place them first, turves *g*, then manure, *h*, again turves, *i*, and finish the roof, *j*, *j*, with smooth sides to prevent rain entering. It is really very interesting work.—G. G.

HEATING GLASS STRUCTURES.

THIS is a matter to which all who wish to keep plants of a tender nature through the winter must attend. In some instances it will mean the fixing of pipes and boilers; in others the careful examination of old fixtures, cleaning and putting them into good order. I am now referring to cases where the heat from pipes is only used during the winter months. Of course, we all know that pipes when allowed to remain full of water when not in use do not deteriorate as much as when they are left empty. Air very often lodges in empty pipes, and if the air-escape pipes are blocked the whole of the pipes will not be filled with water, so that the latter, when heated, cannot circulate. That is the reason why the pipes, in spite of a well stoked fire, do not get warm. Spiders, flies and bees sometimes fill up the ends of the air-pipes; a small piece of wire will soon penetrate and remove any obstruction, and where air-valves only are used, these should be oiled and turned occasionally. Always allow for water rising in the feed cistern where ball-taps are not used, otherwise there will be waste of warm water. Do not paint the pipes with ordinary paint, but use lamp black and boiled linseed oil. It is always wise to study the question of fuel. Much must depend upon the make of the boiler, but for general use I do not find any kind better than two-thirds coke and one-third coal with ashes and slack for banking up at night. It is good policy to bank up on a bright clear fire and to regulate the draught accordingly.—HANTS.

BUSH FRUITS.

UNDER this heading will be found gooseberries and currants, of which latter there are red, white and black. Now is a suitable time to think about forming new plantations, and it is always advisable to trench the ground, at the same time adding a liberal dressing of partly decayed manure, because it should be some years before the necessity arises to discard the bushes. October and November are excellent months for planting all kinds of fruit trees, and the subjects under notice should be planted about 5ft. apart.

The gooseberry is the most valuable of bush fruits, and will bear heavy crops of fine fruit if given good culture, but unfortunately it is often neglected. There are a host of varieties, and it is impossible to grow anything like a collection, so the following names may be useful. Whinham's Industry, a red variety is one of the most popular and reliable; others are Langley Gage, Broom Girl, Keepsake, May Duke, Whitesmith, Dan's Mistake, Telegraph, Lancer, Leveller and Golden Gem. The ideal gooseberry bush should have a clear stem of 9ins., and the branches ought not to be crowded. This fruit is also grown as cordons, with excellent results. They can be placed on fences, and north walls, whereby the supply of fruit is prolonged.

The black currant thrives best in a cool, rich moist soil, but it will also succeed in any ordinary garden, if not given a dry, hot shallow soil. The best varieties include Boskoop Giant, Lee's Prolific, Baldwin's and September Black. Few varieties of white currants are needed and the best is White Dutch. It is sweet and well flavoured. Among the red currants will be found Fay's Prolific, Red Dutch, Comet and La Versaillaise, while Ruby Castle and La Constante are two good late varieties for planting at the base of a wall facing north to supply late fruits.—T. W. B.

TREATMENT OF MONTBRETIAS.

TO get the best results from them one must treat montbretias generously, that is they should have a good situation and the corms set in rich soil, 6ins. or so distant from each other, and 3ins. deep in the soil. Treatment of this kind makes a decided difference to the appearance and vigour of the plants, as when colonies are left for a few years without disturbance, the growths get so thickly crowded that the foliage becomes less in size, while the flower spikes share a similar fate. This, of course, is caused by the corms becoming crowded together, and by the soil in which they are grown becoming exhausted. Plants treated generously will grow to a height of 3½ft., and, indeed, are giants when compared to those seen in overcrowded masses in exhausted stations. The latter part of October or early in November is a splendid period of the year to lift, separate and replant the corms.—DAVID ARMSTRONG.

EDITOR'S TABLE

MR. HARRY WHITE, of the Sunningdale Nurseries, has very kindly sent me specimens of various berry-bearing shrubs. The best was undoubtedly a wonderful berberis of the vulgaris group, which originally came from the Coombe Wood Nurseries. The berries are extraordinary, both in number and for the brilliant coral colour, the brightest I have ever seen. We hope to have a special note on this berberis within a week or two. Another good plant for berry colour is Cratægus persimilis, a relative of C. Crus-galli. C. persimilis usually does not grow to such a large size and makes a neat little tree. The fruit is freely born and is a good bright red. This is also the first time I have seen the fruit of that marvellous rose, R. filipes, one of Mr. Wilson's Chinese importations, which I have mentioned before in THE GARDEN for its quick growing and free flowering qualities. The hips are small, are carried in clusters and when ripe are deep red.

Messrs. Allwood have also kindly sent me blooms of their perpetual border carnations and Allwoodiis. These were all picked in the open and the vases in front of me prove their value for cutting at a time of year when summery flowers are scarce. Of the selfs among the perpetual borders I like Sussex Purple, which is a deep pure shade, and Sussex Supreme, a delicate blush pink and a large flower. There are also a number of the old-fashioned striped carnations raised from Dr. Hogg's old Flakes and Bizarres. I like Sussex Tricolor the best, a pale pink flaked with rose and deep crimson. The Allwoodiis are still crowded with buds and provided the weather is not too hard, they should remain in flower for weeks longer. Phœbe, a good salmon pink, is one of the best of the newer varieties, as also is Nora, a pale rose flaked with deep rose.

INTERESTING ANSWERS

I enclose an apple that I think may be of interest to you and some of my fellow readers of THE GARDEN. *This apple was shown at Shrewsbury Show last month and was then in perfect condition; it was given to a friend of mine, who placed it on a shelf in a pantry. The shelf is deal, unpainted, perfectly clean, and no iron or other metal near.*—H. H. H.

The apple is simply a diseased fruit. The disease affecting it is the "Brown Rot." Apples affected with the fungus that causes this disease, Monilia fructigena, soon turn black when stored under certain conditions, the skin, as in this case, remaining smooth and bearing little or no external signs of disease. But the flesh inside is permeated with the mycelium of the fungus and in a few days time, the characteristic pustules of the fungus will undoubtedly break through the skin of this apple—as always happens after a time. It is fairly common to find these black fruits in the store, though we must add that we have never seen quite such a perfect specimen as this before.

I shall be glad if you can tell me what I can do to prevent my roses (Ophelia in particular) from opening with the petals imbricated and bitten in flowers and buds. The plants are apparently healthy and make vigorous and strong growth and quantities of buds, but I have hardly had a healthy bloom from Ophelia, and the roses next to her appear to be "catching" it. Earlier in the season the buds opened before they were ready, the petals came short and apparently bitten off, and the green seed vessel showed sticking up through the petals. The only insect I have seen on the buds is a small fly, which I occasionally find dead apparently clinging to the tip of a young bud. Earlier in the season the caterpillar which makes the young leaves curl up in spring was rather bad. The beds were sprayed with blue water and winter wash last winter, and the roses have been repeatedly sprayed with Katakilla and paraffin soft soap during the summer.

We suspect that the injury to the rose blooms has been caused by the rose leaf cutting bee, which more usually cuts pieces out of the leaves to form its nest. As the insect does not feed on the roses, spraying would be of no avail, and the only remedy is to locate the nests and destroy them at dusk, when the bees are all in for the night. Although spraying with a good insecticide will check the ravages of the leaf-rolling sawfly, the better plan is to hand pick and destroy the rolled-up leaves when first seen.

Early in the season the first blooms of roses are often malformed as you describe. This is generally due to a slight excess of nitrogen, but it soon becomes balanced, and the next flowers are normal. If the malformation is serious, it may be remedied by applying 1 oz. of superphosphate of lime to each plant during February.

CATALOGUES RECEIVED.

Mr. T. Smith, Daisy Hill Nursery, Newry. A comprehensive catalogue of trees, shrubs and climbing plants. The lists are conveniently divided into sections, such as peat-loving shrubs, conifers, bamboos and grasses, evergreen, deciduous and flowering trees and shrubs. Mr. Smith offers an excellent collection of trees and shrubs, which all shrub-lovers will find of interest.

Mr. Ernest Ballard, Old Court, Colwall. A descriptive price list of new asters of the Novi-Belgii section. All the varieties given have been raised by Mr. Ballard himself, and many good novelties are included in the lists.

Mr. Frank Cant, Braiswick Rose Gardens, Colchester. A descriptive catalogue of roses of all types. All the roses listed are British grown and hints on the treatment of roses are given.

Messrs. James Carter and Co., Raynes Park. List of large-flowered sweet peas for autumn and spring sowing, including novelties for 1926.

Messrs. Laxton Brothers, Bedford. A well compiled catalogue of hardy fruits of all kinds. Careful descriptions and good illustrations are given of the new fruits raised by the well known firm of plant breeders. This catalogue should prove of great interest to all fruit-growers.

Messrs. W. Cutbush, Barnet Nurseries, Barnet. List of hardy fruit and roses.

Messrs. Stuart Low and Co. Bush Hill Park, Middlesex. A catalogue of roses and a special list of fruit trees for home cultivation.

Mr. John Wood, 4, Fitzroy Street, London. A well produced booklet showing illustrations of some of the beautiful rock and water gardens designed by this garden architect.

Mr. T. Hayward, The Chace Gardens, Cosham, Hants. List of hardy border carnations, including the best new carnations of recent introduction.

The Briton Ferry Chemical and Manure Company, Limited, Briton Ferry, South Wales. A booklet enumerating garden and horticultural specialities, such as fertilisers, manures for all purposes, soil fumigants, lawn sand, vaporisers and insecticides. This booklet gives much useful information.

Messrs. Robert Veitch and Son, 54, High Street, Exeter.—Lists of bulbous plants, including narcissi, tulips, hyacinths, scillas, colchicums, liliums, gladioli, nerines, etc. A price list of garden sundries, insecticides and manures is also given, which should prove of interest to all gardeners, and a special list of fruit trees, including trees in pots suitable for orchard house culture, and a list of roses.

Messrs. Dickson Brown and Tait, 57, Cross Street, Manchester.—A catalogue of bulbs of all kinds and a well illustrated and useful booklet on the culture of bulbs in bowls.

Messrs. John E. Knight and Son, Dudley Street, Wolverhampton.—A selected list of bulbs and also seeds for autumn sowing.

Messrs. A. J. and C. Allen, Bowthorpe Road Nurseries, Norwich.—An illustrated catalogue of roses, giving a list of 1925 novelties and detailed descriptions of the best roses of recent introduction.

Messrs. John Jefferies and Son, Limited, The Royal Nurseries, Cirencester.—A comprehensive list of British-grown roses.

FOREIGN.

An excellent little book, called "Beauty from Bulbs," has just reached us from Messrs. John Scheepers Inc., 522, Fifth Avenue, New York City. It serves the purpose of a catalogue, and a very fine one too, but is in reality a treatise on the leading varieties of bulbs for outdoor and indoor culture. The book is a well arranged one and contains numerous concise cultural articles on our different bulbs. Much useful information is given as to varieties suitable for woodland and border planting and also for the rock garden. The selection of varieties of the different sorts is a large one, and intending buyers should find their wishes gratified. Numerous half-tone and many coloured reproductions, which occur throughout the book, are exceedingly well executed and considerably enhance the value of the volume. It certainly stands as an excellent little brochure and serves to indicate how attractive a catalogue may be made. In its attraction lies its merit, as, no doubt, the publishers are fully aware by this time. We would recommend all our American readers who are bulb enthusiasts to procure a copy, and it certainly would be of interest to many on this side.

Messrs. L. Lemoine and Son, Rue de Montet, Nancy, France.—An interesting catalogue giving lists of greenhouse plants, ferns, an excellent collection of new and rare hardy shrubs, and perennials. Many fine varieties of asters, delphiniums, irises, phloxes and hydrangeas are given.

Mr. Carl Purdy, Ukiah, California. An interesting list of Californian bulbous plants. Many of these are of great beauty and succeed admirably in English gardens. Such bulbous plants as brodiæas, camassias, calochorti and many Western species of lilies are included. Another catalogue of herbaceous, perennial and alpine plants has come to hand.

Messrs. C. C. Morse and Co., San Francisco. A pamphlet offering three beautiful early-flowering Spencer sweet pea novelties. These three new sweet peas are valuable assets to the many varieties which are now in commerce.

Grandis Roseraies, Orleans, France. A general catalogue of new and rare hardy ornamental shrubs, perennials, clematises, peonies and roses. A fine and extensive collection of flowering and berried shrubs is offered.

We are asked to remind the readers of THE GARDEN that the British Carnation Society's show will be held at the Royal Horticultural Society's Hall, Vincent Square, on December 1st, 1925. The following new carnation, Lady Margaret Boscawen, has been registered by Messrs. Low and Shawyer, The Nurseries, Uxbridge. Colour clear pink, good stem and calyx, free and clear, crops freely, and flowers well up to average size.

THE ROSE—OUR NATIONAL FLOWER

LONG before Chaucer wrote:

The savour of the roses swote
Me smote right to the herte wrote,

roses were popular in England. Like in many another popular flower of the Middle Ages, the pleasure derived from them was probably that of taste and smell rather than beauty. Everyone knows that most of the early flowers were grown primarily for purposes of utility, but few realise how much the rose was used not only in scents and unguents but also for cooking. The flowers were used in many a conserve, one of which went by the attractive title of "rede rose," and a popular dish at one time was "sane saracen," of which the hips were the principal ingredient. Even in the time of Charles II, Sir Kenelm Digby gives the recipe for a "Conserve of Red Roses," and attractive it sounds too, although, perhaps, rather sweet for present-day tastes.

Probably the most reliable early description of the cultivation of the rose in England is to be found in Bartholomew's "De Proprietatibus Rerum," which was written about 1260. In the first English translation is quite a long description of the plant and its uses. "And by often chaunging and tylthing the wylde rose tornith and changith into a very rose. And the rose of ye garden and the wylde rose ben dyvers in multitude of floures; smelle and colour; and also in vertue." And again: "Among all floures of the worlde the floure of the rose is cheyf and beeryth ye pryse. And by cause of vertues and swete smelle and savour. For by fayrnesse they fede the syghte; and playseth the smelle by odour, the touche by softe handlynge."

We have to advance many years before a list of roses is given, or, indeed, many varieties are mentioned. Nicholson gives the following roses as actually being in cultivation in Britain before 1600: R. alba, R. centifolia, R. damascena, R. gallica, R. moschata, R. rubiginosa, R. sempervirens. There is, however, no list of varieties as opposed to species which were in existence before 1700. Although Gerard does not actually mention the name York and Lancaster, there is reason to believe that it was in existence in his day. In his herbal of 1597 he says, "It is the honor and ornament of our English Scepter, as by the coniunction appeereth in the uniting of those two most royal houses of Lancaster and Yorke. Which pleasant flowers deserve the chiefest place in crowns and garlands. The double white sort doth growe wilde in many hedges of Lancashire in great abundance, even as briers do with us in these southerly parts, especially in a place of the countrey called Leyland, and in the place called Roughfoorde not far from Latham."

Certainly at some period of the seventeenth or eighteenth centuries the cultivation of the rose must have increased enormously, far more than appears in print, for Mrs. Evelyn Cecil mentions that in the year 1826 the famous firm of nurserymen called Loddiges issued a catalogue in which no fewer than 1,393 species and varieties of rose are mentioned. This number seems to be large, and it would be interesting if some rosarian would check it and see of what these roses consisted and if any of the hybrids are still in existence at the present moment. It seems almost incredible that so many varieties were in existence before the American and Asiatic species had time to influence their breeding, for the great influx of rose species took place between 1790 and 1840, and some years must naturally pass before these would be used for hybridising purposes.

Since Loddiges' time, Paul and many others have perfected the shape and colour beyond all belief, although in the process of this perfection some of the fragrance has been lost. It is pleasant to think that old-fashioned roses are coming into fashion again and that there is a distinct vogue at the present time for the single. Far from the popularity of the rose being on the wane, it is increasing by leaps and bounds; the first order for plants that is placed for a new garden is invariably for roses. This love must be partly caused by inherited instinct, for no other country possesses a single flower of such national popularity. The Japanese, whose love of flowers must be as great as our own, apportion about half of their affection to the cherry and half to the chrysanthemum; but the rose allows no rival in our affections. For reasons of space or soil, some of us may not be absolutely successful with its cultivation and we may specialise in other plants, but that does not mean that we love the rose any the less. They are plants of quality which in their various forms are invaluable for every possible kind of gardening. We can never have too much of the rose as a flower for indoor decoration. We owe a debt of real gratitude both to the plants and to those who raise them. E. H. M. C.

SMALL GARDEN DESIGNS, by R. V. Giffard Woolley.

THE BREAKING OF TULIPS, by C. W. Needham.

THE AUTUMN TREATMENT OF LAWNS.

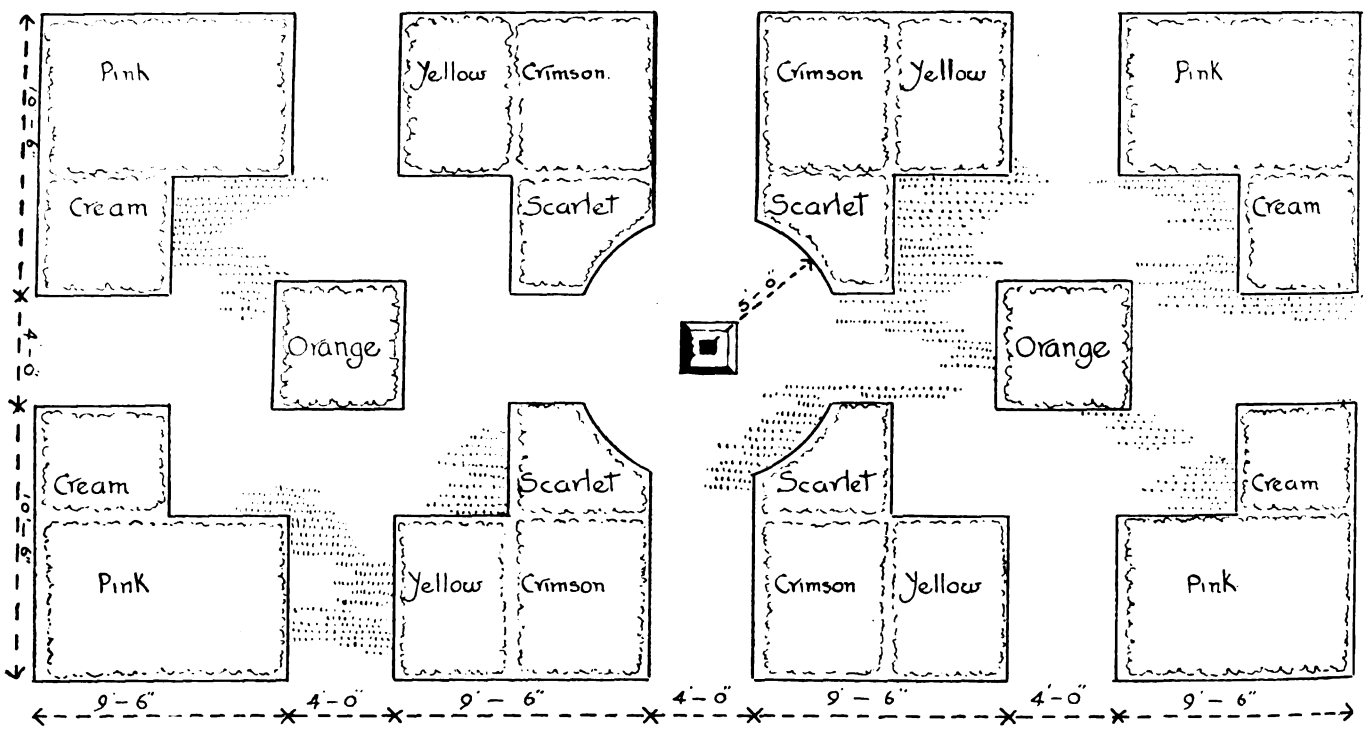
Digitized by Google

PLANNING & PLANTING A SMALL ROSE GARDEN

A GARDEN consisting entirely of roses is a practical and desirable proposition, but an English garden without roses is inconceivable. No other flower combines the almost infinite range of colour gradation with a flowering period lasting from early summer to late autumn, and a fragrance unequalled by any other occupant of the garden.

It is not always, however, that roses are planted to the best advantage. One sometimes finds them in scattered masses mixed with shrubs or herbaceous plants, or in curious-shaped beds dumped at random into odd corners of the garden, but this is not doing them justice. The rose possesses so many attractions and is in a class so entirely unique that it demands a portion of the garden to be devoted exclusively to its cultivation. Moreover, the rose is not a plant which cares to associate too closely with its neighbours. It has been called the Queen of Flowers, and it would appear from its objection to mixing with other plants that it realises its lofty position in the flower world and insists on that aloofness from common things which has always been considered, rightly or wrongly, to be a royal attribute.

There is a very strong argument in favour of making a rose garden one in which the lines are more or less formal, and this applies particularly to a situation where the area



is somewhat limited. Roses look at their best when grown in blocks or masses of one sort, and this little formal garden which I have designed to suggest a pleasant arrangement wherein at least twenty-two varieties of roses can be grown in such a way that each will assist the other by colour combination can be modified to suit an area somewhat smaller or considerably larger.

The total area occupied by the rose garden is 50ft. by 25ft., and a glance at the plan will show that it is possible within such an area to grow a very fine selection of roses. I always think that one cannot be too careful in combining the colours in a rose garden. Take, for instance, the crimsons and pinks. Planted side by side, these detract each from the other, whereas crimsons and pale yellows always unite perfectly. There is nothing to object to in the association of yellows and pinks, and the pinks and creams or very pale yellows make a very soft and happy combination.

In this little garden I am suggesting that the strong and warm colours are massed in the centre of the design, and thus we get four blocks of crimson connected to four of yellow, while in the interior they shade away to four smaller groups of bright scarlet. The isolated beds of orange will have the effect of keeping the central mass of warm colours to themselves. In the four L-shaped beds in the corners the pinks will be seen nearest the yellow, and will shade away to smaller groups of cream and very pale yellow.

If the area were a little larger, I should have preferred making the paths 5ft. wide instead of 4ft., because 5ft. allows two people to walk side by side, whereas 4ft. scarcely permits this. Also, if the area were a little larger the beds could be increased in size without destroying the cohesion of the elements forming the general design.

Now, a few words about the paths. In my design I have shown the whole of the rose garden lying in a lawn of mown grass, and there is not the slightest shadow of doubt that this is by far the most satisfactory effect, looking at it from the æsthetic point of view. If the garden is large enough to surround it as suggested in the plan by borders of either herbaceous plants or flowering and foliage shrubs, then any hard paths which are required can be placed outside these borders, but if the garden is so small that it is necessary to make dry paths inside this enclosure, I would restrict such an effort entirely to the surrounding path, that is, between the borders and the rose beds. I would urge strongly how important it is that this colour grouping should be seen, relieved by the cool green carpet of closely mown turf.

In such a design as is presented here it is necessary to introduce some central object, which can either be a garden ornament or a shrub, provided it is remembered that the shrub will grow, that the area is limited, and the choice must therefore be one which will not usurp the necessary width of path surrounding it.

With regard to the varieties which can be planted in such a garden, these would depend to a very great extent upon local conditions. There is no doubt whatever that some roses succeed better in some localities than in others, and in making the following suggestions of varieties suitable for such a garden I do so with the idea that many people will have their own preferences with regard to varieties, and some of the sorts I mention will be better omitted on account of the local conditions.

Crimson.—General McArthur, Etoile de Hollande, Lord Charlemont, Col. Oswald Fitzgerald, Hawlmark Crimson, Hugh Dickson and Hoosier Beauty.

Scarlet.—Charles K. Douglas, K. of K., Hortulanus Budde, Red Letter Day, Templar and Lady Maureen Stewart.

Orange.—Emma Wright, Sunstar, Independence Day, Irish Fireflame (single), Irish Elegance (single), Henrietta, Frances Gaunt, Flame of Fire and Lamia.

Digitized by Google

Deep Yellow.—Mabel Morse, Golden Emblem, Christine, Florence L. Izzard, Mrs. S. K. Rindge, Mrs. Wemyss Quin, Sovereign and Rev. F. Page Roberts.

Pale Yellow and Cream.—Elegante, Harry Kirk, Miss Willmott, Mrs. Beckwith, Melody, Mrs. Henry Balfour and Nellie Parker.

Pink.—Mrs. Henry Bowles, Mme. Butterfly, Rose Marie, Mrs. Henry Morse, Mme. Abel Chatenay, Mrs. George Shawyer and Charles E. Shea.

Salmon and Cerises.—Lady Inchiquin, Los Angeles, Cheerful, Mrs. Redford, Lady Dixon Hartland and Betty Uprichard (orange and salmon pink.)

For such an arrangement as I have suggested the above is a sufficiently comprehensive list from which to select, but to say that it is even representative of all that is good in roses would be absurd. A dozen similar lists could be compiled, and the actual choice of varieties must therefore be a matter of personal taste.

GEORGE DILLISTONE.

THE POLYANTHA POMPON ROSES

THERE are few better bedding plants than polyantha pompon roses. Indeed, this class of rose can boast of almost every good quality required of a bedding plant. Brilliancy and diversity of colouring, a long season coupled with great freedom of blooming, excellent foliage, compact and upright habit and, in addition, absolute hardiness, an attribute not possessed by many so-called bedding plants.

Unfortunately, they lack, with few exceptions, the endearing quality of fragrance. This doubtless detracts from their value as roses, for a rose *should* give the sweetness its very name suggests. Gardeners, however, seldom ask for fragrance in their bedding plants. The popularity of the begonia, the dwarf single dahlia and the pentstemon proves this. To me, the heliotrope, the stock and the verbena are more attractive than the dahlia, the begonia and the pentstemon just on this account; and because I hold sweetness as a most desirable attribute in a flower and because of their comparative lack of form I cannot rank polyantha roses with teas or hybrid teas. Not that they are entirely exempt from fragrance. Among the whites several are honey-scented, notably Yvonne Rabier; and the pretty rose-coloured Ellen Poulsen has a refreshing sweet briar fragrance. Curiously enough, it is among the reds and crimsons that fragrance is entirely absent. But in spite of this drawback, when considering them as roses, they are extraordinarily useful and effective for small beds.

AMONG THE BEST OF THE POLYANTHA VARIETIES IS ROSE CORAL PINK.

ANOTHER EXCELLENT NOVELTY, ORLEANS ROSE, CARRYING LARGE TRUSSES OF DEEP ROSE PINK BLOOMS.

We planted last November on our front lawn a long, narrow bed with the single appropriately called Pink Delight. From June till the present time (mid-September) this bed has been one of the brightest spots in the garden. The dark olive green foliage sets off very charmingly the big sprays of clear bright pink blossoms, and the plants so far have been quite untouched by mildew or black spot. Immunity from diseases, such as mildew, black spot and stem fungus, is another great asset of these dwarf polyanthas.

Again, few varieties are much affected by rain, their blossoms for the most part being composed of small petals of good substance which soon recover from the effects even of heavy showers; this, naturally, adds very much to their value as bedding plants, especially as the season advances. There are one or two exceptions. The white Katherine Zeimet has rather papery petals which quickly turn brown if exposed to heavy rain. On the other hand, the charming Little Meg, also a white, has smooth, solid little petals which resist rain and keep their purity in quite bad weather.

Many of the so-called dwarf polyanthas, such as Leonie Lamesch and Yvonne Rabier, will grow into big bushes. Only last week we saw some plants of Leonie Lamesch in the late Canon Ellacombe's

Digitized by Google

garden at Bitton covered with their reddish copper-coloured blooms, which were quite 5ft. high, and I have seen some of the fragrant white Yvonne Rabier in our president's garden in Canterbury which, from memory, I should say were even bigger. These are not the kinds to be recommended for bedding. In the Rose Annual for 1920 Mr. George Taylor has pointed out that there are certainly two distinct types of "poly poms," a tall and a dwarf-growing type. He instances Gloire des Polyantha (1888) as being in habit an ideal dwarf variety, and Leonie Lamesch (1899) as a type of the tall-growing kind. For small beds such as I have in my mind—beds on a lawn that will hold from nine to a dozen plants—it is to the really dwarf type we shall look.

During the last ten or twelve years quite a number of these have been introduced, but we can still do with a greater variety of colours. White, bright pink, rose and crimson are fairly well represented, and during the twenties an advance has been made in the introduction of such delicate shades of pink as those of Coral Cluster and Juliana. But we still want a really first-class yellow. Mr. Easlea's Gwyneth is a step in the right direction. It has fine foliage, makes good sprays, the flowers are sometimes bright yellow and are very prettily shaped in the bud. We have only a few plants of Gwyneth, but I am inclined to doubt whether it would make a really showy bed in the way that Mrs. Wemyss Quin or Christine does. Then, so far as I know, we have no "poly pom" with the large apricot tints of Los Angeles and W. F. Dreer, or the deep coral rose of Betty Uprichard and others. Nor, though we have, as I said before, some good crimsons, have we yet anything that can compare with the brilliant scarlet crimson of K. of K. or Red Letter Day. Therefore there is plenty of work for our hybridisers among this useful race of polyantha pompons. They have done so much for us in the past that one can feel confident their efforts will not relax till they have provided us with the many beautiful tints we are asking for, and let them also bear in mind that fragrance would add immensely to the attraction of these little bedding roses.

Before concluding these short notes I will add a list of those varieties we have found most useful for bedding purposes.

WHITES.

Anna Maria de Montravel.—Very dwarf.

Katherine Zeimet.—Dwarf and free.

Joan of Arc.—Sweetly scented and very free blooming.

Yvonne Rabier.—Sweet scented. Will stand pruning, but is more suitable for growing as a free bush.

Little Meg.—Prettily shaped flowers, glossy foliage.

LIGHT PINKS.

Coral Cluster and *Juliana.*—These two are very similar. As seen growing at Wisley, Juliana appeared to have a slightly better habit, and it is perhaps less given to sport. Both at their best are very pretty and delicate in colouring.

Perle Orleanaise.—Soft creamy pink, very dwarf.

BRIGHT PINK.

Dorothy Dix.—One of the newer varieties with rather large flowers for its class.

Ellen Poulsen.—Bright rose, one of the best, with prettily shaped, fragrant flowers. Excellent for growing under glass.

Mrs. W. H. Cutbush.—Clear pink, very pretty.

Orleans Rose.—Extra large trusses of deep rosy pink flowers.

Pink Delight.—Single, bright pink, very free, constant and effective. In some respects this variety is nearer the hybrid teas than the "poly poms."

CRIMSON.

Eblouissant.—One of the dwarfest and prettiest. Sprays of dark but bright crimson flowers. In foliage and colour it much resembles the Chinas.

Edith Cavell.—So far the best crimson "poly pom." Its fine trusses of dark crimson flowers keep their colour well except in very bright sunshine, when they are apt to "burn," but they do do not "blue.'

Kosters Orleans.—In habit very like Orleans, in colour a lighter crimson than Edith Cavell and with rather smaller trusses.

Reine Elizabeth is similar to Edith Cavell and as we have grown it, so much so that it hardly seems necessary to grow both varieties. The flowers are perhaps a little farther apart in the bunches, but they "burn" in just the same way as the older Edith Cavell.

Triomphe Orleanaise.—Bright light crimson with a touch of crimson lake, big trusses and almost constantly in bloom.

YELLOWS.

There is no really good yellow bedding "poly pom." *George Elger* and *Gwyneth* are probably the two best, but both have the failing that in bright sunshine the flowers lose their golden tints and open almost white. The old *Perle d'Or* has very prettily shaped buds of nankeen yellow, but it is not suitable for small beds and should be grown as a bush and only slightly pruned. The same remark applies to the pretty shell pink *Cecile Brunner.*

There are many other varieties, but I think those mentioned in my list are the best for general effect in small gardens. Possibly I should add the orange sport of Jessie—*Orange King.* It is a new break in colour, but to my mind the flowers are too stiff and button-like to be pleasing. WHITE LADY.

THE IMPORTANCE OF THE MODERN RAMBLER

WE have become so familiar with rambler roses in our gardens, that one can scarcely imagine how much we are indebted to the introducers of the lovely varieties that are met with on every hand. Yet the writer can remember the time, prior to the advent of Crimson Rambler and Dorothy Perkins, when one had to be content with the Ayrshire, sempervirens and Boursault roses to clothe arches and pergolas, and even to-day the beautiful old Félicité-et-Perpétue and Bennett's Seedling are much valued for their sweet aromatic fragrance, which, unfortunately, is lacking in many of the modern ramblers.

We must, however, not be too insistent in our desires for fragrance, providing we obtain compensations in a wealth of blossom and glorious foliage. It was a happy inspiration of our American cousins to use the procumbent species, Rosa Wichuraiana, as a seed parent, crossing it as they did with some of the lovely tea and hybrid tea roses, and, strangely as it may seem, the best of the modern ramblers are those that have R. Wichuraiana as their seed parent. One would have thought that by using some of the best of the modern kinds as seed parents there would be evolved even greater productions, but it is not so.

One of the most successful hybridisers, Mons. Barbier, assured the writer that his best successes were obtained from R. Wichuraiana as a seed parent.

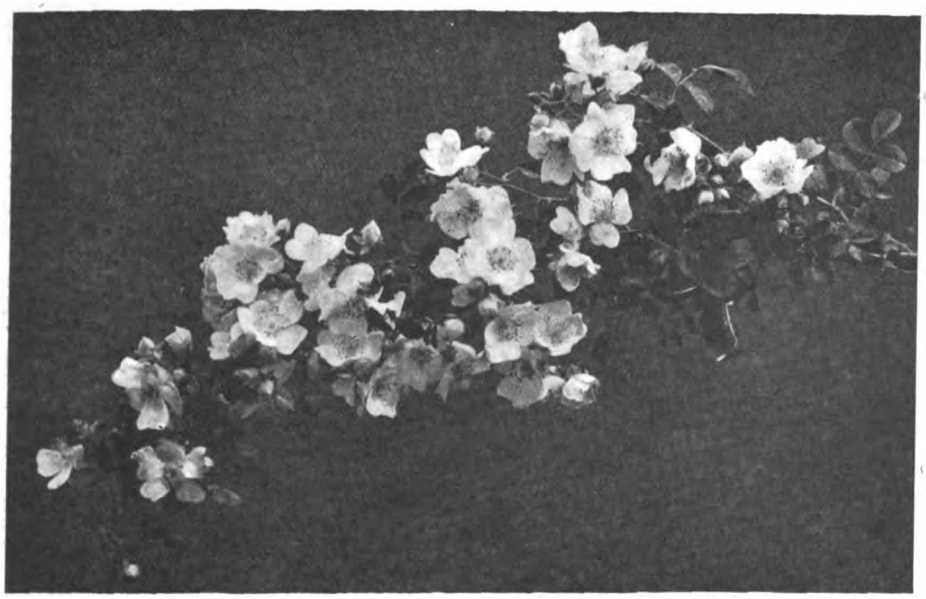
That this is not an absolute necessity is evidenced by the fact that Dr. Williams obtained the very beautiful Emily Gray by crossing Jersey Beauty with the monthly rose, Comtesse du Cayla. Here we have a glorious yellow, the best to date, and one that bears flowers almost as large as a Mme. Ravary. When grown so as to form a sort of screen over a sunk garden the effect is a most telling one, and, in midsummer, the ultimate result is a glorious mass of golden buds and blossoms.

The fortunate individual who succeeds in raising a really golden rambler with clusters like Dorothy Perkins, will confer a lasting boon upon all rose lovers, for although Emily Gray is so very beautiful, there is not that profusion of blossom that one obtains with the Dorothy Perkins tribe.

The really essential requirement of a modern rambler is that it should yield huge clusters of flowers. Far too many of recent introductions fail in this. They have lovely colours, but the clusters are meagre and wanting in decorative effect. This is more noticeable in the yellow and orange shades.

Although Dorothy Perkins is met with on every hand, there is nothing more beautiful than a well clothed arch or pillar of this delightful rose. It is most gratifying to observe that the cultural hints so often mentoined in THE GARDEN have had good results, and even the novice is aware that he must not spare the pruning knife if he would have the best results from rambler roses. Many individuals who merely have a

Digitized by Google



THE HANDSOME ROSE-PINK BLOSSOMS OF ROSE KEW RAMBLER.

small garden may have lovely pillars and arches of these roses if they are careful to cut away old growths freely. Even if only three or four good ripened young growths are retained, the grower is rewarded with those delightful long trails of blossom that charm the eye. Whereas if the plants are allowed to grow at will they soon become a tangled mass of growth with resultant small clusters of flowers and a wealth of mildew to boot.

I cannot impress upon my readers too much the necessity of preparing good large holes wherein to plant ramblers. They need a good depth of well worked soil for their roots so that growth is free and unchecked.

In preparing the positions for rambler roses it is essential to add some good manure to the lower spit of soil, so that when the roots commence to penetrate they will find a larder of nourishing food. I have found nothing better than Wakeley's Hop Manure. In these days of motor transit it becomes exceedingly difficult to obtain farmyard manure, but Wakeley's supplies just that humus and stimulant so necessary to vigorous growth.

I have found the best results follow its use when thus incorporated with the lower soil.

If used near the surface the rain dissolves it too rapidly and it is not advisable for newly planted roses to have strong stimulant until the new roots are formed, and even then it is better for the food to be below, then they can search it out as required. Amateurs should remember this, not only as regards Wakeley's Hop Manure, but all artificial manures.

Of course, when the roses are established then a top dressing of "Wakeley's" is decidedly beneficial.

Beside the usual arch or pillar, there are many ways in which rambler roses may adorn the garden, such as when budded on tall briars to form weeping roses or planted in a border and allowed to droop over walls. They are seen to great advantage when tumbling over banks by lakes and ponds, and for forming hedges, nothing can surpass their wondrous beauty. At Aldenham House Mr. Beckett has made a glorious hedge which is of considerable length. Not only do they serve the usual purposes of a hedge but in addition provide a wealth of colour and beauty.

Rambler roses can be profitably employed in the background of perennial borders. I remember some years ago the late Mr. Norman used the old Crimson Rambler to great effect in such borders, grouping the stately delphiniums near them, and there are innumerable methods of utilising modern ramblers. I have seen them flourishing in large kitchen gardens, lending a brilliant tone to what otherwise is a somewhat uninteresting feature of a garden, especially to the flower lover.

I think much of the beauty of ramblers is lost upon ordinary pergolas. The best method is to have a series of arches as at Kew and link up the arches with chains or rope and allow some of the growths to cover same. In this case one obtains the pillars of the arches well clothed and, of course, properly in view, but when an overhead density of growth is allowed, the pillars of the arches suffer thereby.

It is not so generally known as it should be that where the growths annually retained send out lateral growths, such laterals should be cut back to two or three eyes at pruning time in March. This results in far superior clusters of blossom than if these laterals are retained a good length.

I would urge my readers to avoid planting ramblers upon hot walls. Even the shiny leaved sorts, such as Albéric Barbier, are far happier upon an arch or pillar and the rougher leaved sorts, such as Crimson Rambler and Blush Rambler, are a terrible prey to red spider and mildew when planted near a wall.

Owners of large parks would do well to plant some of the lovely modern ramblers in clumps, and allow them to tumble over old roots or tree stumps. Even in the wild garden they are delightful, providing one selects a fine open spot which is exposed to the sun for the greater part of the day.

In conclusion I would just name a few of the more recent kinds really worth growing, for it is not necessary to go over the older varieties. The novelties are Jacotte, Albertine, Violetta, The Beacon, Chastity, Ile de France, Romeo, Clematis, Mary Wallace, Dr. Robert Hucy, Fraicheur, Snowflake, Yvonne, Beauté Orleanaise, Kew Rambler, Purity, and, of course, Paul's Scarlet and the delightful Mermaid.

SWEET PEAS: ADVANTAGES of AUTUMN SOWING

IN the spring one occasionally finds a sweet pea plant growing on land on which sweet peas were grown the previous year. Such plants are, of course, "self sets" from seed which fell to the ground and germinated during August, September or October. Nature evidently intended the sweet pea to perpetuate itself by an autumn germination of its seeds, and certainly the stray "self sets" invariably impress one with their very robust and "hard as nails" appearance.

It is now generally recognised that, on the whole, particularly in the southern half of the British Isles, autumn-sown plants give better results than those from a sowing in the early months of the year. They not only bloom much earlier and grow away more readily, but often continue to flower weeks after the spring-sown have finished. Their colours are more brilliant, and through a hardier, stronger constitution and much more extensive root system they withstand adverse weather conditions to a greater extent. In my opinion one of the greatest advantages of autumn-sown plants as compared with spring-sown is the facility of the former to ward off attacks of disease during the flowering period. So-called "streak" is undoubtedly more frequently met with in spring-sown sweet peas.

There would be fewer failures and disappointments among amateur growers if sweet peas, speaking generally, were given more hardy treatment. "Coddling" in any shape or form is well-nigh fatal.

SOWING IN THE OPEN GROUND.

In the first place, I cannot recommend this method where expensive seeds are concerned: it is a little too risky; but a good mixture of the better Spencer varieties, such as may be purchased at about 1s. per ounce, will yield very pleasing results nine seasons out of ten if sown where they are to flower. An ounce will make a thick hedge 8yds. or 10yds. long if sown in drills made with a hoe 1½ins. to 2ins. deep on ground that has previously been deeply dug, or trenched, and liberally manured. If two or more rows are required, allow at least 5ft. between them. After sowing the seeds and covering them in, dust a dressing of soot on the surface. Any time between the end of September to the third week in October will suit most districts for sowing, and the quantity of seed mentioned will allow for depreciations by slugs, birds, etc. It will be a simple matter to thin out if necessary in the spring. When the seedlings appear, birds may be troublesome in some districts, and these can be warded off by means of the well known wire pea guards, or by stretching strands of black cotton just above the plants. Lime, old soot or finely sifted ashes sprinkled along each side of the rows will check slugs and snails. It is wise to give the young plants some measure of support about the beginning of December, and this may conveniently be done with short sticks or twigs about 1ft. high. They will be all the better for this support, for if left to blow about, frosts are more likely to cut them at the base where the haulm has bent over. The sticks themselves afford no small degree of protection.

This is the method usually practised by market growers of cut bloom who sow in the open fields, allowing about 1lb. of seed to every 100yds. run of row. In the Midlands they commence picking their flowers about the last week in May.

SOWING IN POTS OR BOXES.

The majority of successful growers and exhibitors sow in pots or boxes in a cold frame between the last week in September and the last week in October. Any good porous soil that is not too rich will do admirably as a potting medium, and in many cases well decayed leaf-mould and silver sand may be mixed in with advantage. I generally use 48-sized pots, but smaller sizes will do just as well. Boxes should be about 6ins. to 8ins. deep. Crock the bottoms of the pots and make drainage holes in the boxes, and sow about ½in. deep, allowing roughly two to three square inches of surface space to every seed. Some of the black-seeded varieties have hard, flinty seed-coats, and these should be slightly chipped with a penknife or file to ensure an even germination. If the potting soil is fairly moist an immediate watering is unnecessary. Avoid over-watering, or some of the white-seeded and wrinkled varieties may rot during germination, particularly if the weather is cold. On the other hand, do not allow the soil to become dry. Rolling the seeds in red lead or soaking them in paraffin to prevent the annoying attentions of mice I cannot recommend. The best and safest way is to set a few of the little "break-back" traps baited with bacon-rind, bread or cheese, on the top of the pots or boxes directly they are sown. Mice will not prove a nuisance after the seedlings are an inch high.

Plunge the pots in the cold frame to their rims in soil, peat or coal ashes, to conserve moisture and keep frost from their roots. Leave the glass frame-lights on until the young plants appear through the soil, then remove them entirely and never replace except during very wet or frosty spells. Even during very hard frosts, prop up the lights about 6ins. at the bottoms during the middle of the day. *The great secret of success in autumn sowing in cold frames or a cold greenhouse is to grow the young plants along very slowly and hardily, giving all the light and air possible* and only enough water to keep them going.

A few short twigs will keep the plants upright, for if allowed to blow about they readily rot off near the soil level where they bend. Prevent the attack of birds by throwing fish netting all over the frame. Many good growers pinch out the tops or growing tips of the seedlings when they have made their third pair of leaves. This keeps them sturdy and causes the growth of strong basal side shoots.

Hardy treatment should be one's aim, for "drawn-up" spindly specimens, the result of "coddling," will never be worth their garden space. C. H. A. S.

(To be continued.)

NOTES OF THE WEEK

THE EMBANKMENT GARDENS.

Because I travel on the District Line
My thanks are offered for a gracious thing,—
The gardens of the Rail, where—thought divine!—
Some happy hand has found a flower to fling;
Beyond the tired faces out from town,
I see them streaming past me, green and brown.

Congratulations, gard'ners, on your beans,
Your honest cabbage, and your marrows there;
But most because you flanked your winter greens
With beauty,—that you found the space to spare.
For, while the packed compartment reels and rocks,
My heart is happy with your hollyhocks!

DOLF WYLLARDE.

HARDY FUCHSIAS.

AN ANSWER TO MR. CAHEN'S ARTICLE CALLED "A PLEA FOR THE FUCHSIA."

IN some parts of the country it would be unwise to state that fuchsias are hardy, but in many districts they will succeed and form quite large bushes. Around Chepstow, on the borders of Monmouth and Gloucestershire, some fine examples can be seen, especially in cottage gardens, where they are allowed to develop and attain a height of eight or more feet. Certainly they deserve to be given a trial in many more gardens, as few plants make a more brilliant display in late summer and autumn than the shrubby forms of the humble fuchsia. They are laden with flowers, and even the buds are most conspicuous, and add considerably to the beauty of these plants. They are also useful as cut flowers, and this autumn I have seen some pretty dinner-table decorations which consisted entirely of Fuchsia gracilis. Although they are useful in the shrubbery border, a bed is much more effective; isolated specimens in the rock garden add a note of gaiety at a period when brightness is at a discount. There is no question about their cultivation; they will succeed in almost any soil; but if there is a doubt about their hardiness, a sheltered position should be chosen. In many districts they will be killed to the ground during the winter months, but, unless the weather is very severe, shoots will appear from the old stools in the spring. These growths will attain a height of several feet, and flower freely so long as the weather is open. Perhaps the most useful of all is F. Riccartoni; certainly it is one of the hardiest, and it bears a profusion of brilliant red flowers on twiggy growths, and remains in full beauty for many weeks. It is said to be of hybrid origin. A South American species is F. macrostemma. It has a rich scarlet calyx and purple petals, and there are also

Digitized by Google

BUTTERFLIES ON SEDUM SPECTABILE.

many forms of this desirable plant, such as gracilis (with its slender red stems and bright crimson flowers) and corallina.

A tiny creeping fuchsia is F. procumbens, suitable for the rock garden, the blue berries being a distinct feature of this plant. It would be interesting to know if anyone has succeeded in raising hybrids in which this species figures as a parent.—T. W. BRISCOE, *Chepstow*.

CLETHRA ARBOREA.

I HAVE visited many good gardens in the south and west of this country, where many tender and choice flowering shrubs are well grown and cared for. But rarely do I find that lovely sweet-smelling evergreen shrub Clethra arborea among those collections. While agreeing that it is rather a tender subject and not suitable for general planting, yet I feel sure it is far hardier than many lovers of choice flowering shrubs conceive, and if given the protection of a wall would succeed in many places where least expected. There are two very fine plants growing in these gardens, one facing south, the other occupying a south-west position, and both plants have passed through several winters unprotected and rarely fail to blossom freely. The flowers resemble the lily of the valley, and are produced in June and July. They thrive in rich loamy soil with the addition of leaf-mould or peat. Cuttings taken from half-ripened wood during June will root freely if inserted in sandy soil and placed in a cold frame.—F. W. RICH, *Plympton*.

COUVE TRONCHUDA

(THE PORTUGAL CABBAGE).

I AM missing Couve Tronchuda from gardens where it was once grown, and wonder whether its culture, like that of the colewort, has not been abandoned. It cannot be said of it that it was ever very popular, and one is surprised at this, considering that it comes to perfection in October, when the last dish of runner beans has been gathered, and before one feels disposed to commence with winter greens. I fear that the average gardener, who may not have made the acquaintance of Couve Tronchuda, loses sight of the important fact that nearly all the leaves are edible and make an agreeable dish when properly cooked. It takes up more room, it is true, than most of the brassica tribe, but against that one must bear in mind that practically all the leaves are serviceable. It will not stand hard frost for long, but one may rely on it cropping up to about Christmas. People to whom I have given a sample for the table express themselves as satisfied, and ask why it is that greengrocers do not offer the vegetable for sale. That is another point which needs elucidating! If catered for, would not the supply of this very useful autumn vegetable create a demand for it? I am inclined to think so!—CLAREMONT.

BUTTERFLIES ON SEDUM SPECTABILE.

THE accompanying photograph was taken in my garden at the end of September last year, and represents an extraordinary picture. For a period of about a fortnight, during every spell of sunshine, the plants of Sedum spectabile were visited daily by dozens of gaily coloured butterflies. At one time twenty-five were counted on one plant alone, some with their wings outspread, some gently fanning in the sunshine, others quietly at rest. The commonest visitors were the gaily variegated Tortoiseshells, closely followed by the velvety Red Admirals, while there was usually at least one Peacock among the guests. After crawling over the flower-heads sipping nectar all the time, they would flutter across to the stone path, seemingly half drugged, and there bask in the sunshine, only to return in a little while to the scene of the feast.—W. WILLIAMS, *Barry, Glamorgan*.

ARALIA CHINENSIS.

ARALIA chinensis was one of the earliest of Chinese shrubs to be introduced into England and was described and named by Linnæus. It is undoubtedly one of the most ornamental of all shrubs of large foliage, and is common in gardens and public parks—it is often grown in London squares—and so requires no advertising. The long arching pinnate leaves are always decorative, and the large panicles of small white flowers are an added attraction in August and September, when flowering shrubs are few and far between. There are several varieties in cultivation, among the most common being var. mandschuricus, sometimes known as Dimorphanthus mandschuricus. The object of this note is not to advertise a plant that is already well known, at least in the south, but to point out that I do not agree with the dictum of almost every writer on shrubs, that it is of doubtful hardiness. In my garden in Perthshire it is almost a curse. It was originally planted many years ago in a sheltered position, according to instructions, and its suckers, which are often 6ft. away from the parent, have to be rooted up every second year. It has reached a height of 14ft. or 15ft., and, although handsome, tries its hardest to strangle its neighbours. Some of the suckers have been removed to an exposed position which is exceedingly dry in summer, and are still thriving. It is, indeed, an admirable plant for the wild garden, where it can sucker away to its heart's content; but it is dangerous to plant it in a sheltered position where space is valuable. Undoubtedly aralias take a long time to establish themselves. I have another species, F. 1428, collected from comparatively low down in Burma. For four years it was cut down to the ground every winter, and several times was almost consigned to the rubbish heap as being too tender. Last year it suddenly shot away: the stem survived the winter without protection, and now it is nearly 6ft. in height. It has taken four years to acclimatise itself. Perhaps similar experiences have led to the doubt of the hardiness of Aralia chinensis.—E. C., *Perthshire*.

HELIANTHUS SPARSIFOLIUS VAR. MONARCH.

PROBABLY the usual name in our British catalogues for this fine plant is simply Helianthus Monarch. I am told that it is identical with, or very similar to, one which Cannell introduced under the name of sparsifolius and which, for a considerable time after its introduction, enjoyed a well merited popularity and then became neglected. I have had my eye on it now for three years and, although I have not grown it myself, I have seen it growing and I have seen it in

THE WHITE PLUMES OF ARALIA CHINENSIS.

Digitized by Google

ONE OF THE LARGEST AND OLDEST SPECIMENS OF THE ETNA BROOM.

a cut state at exhibitions. On every occasion I have made a point of asking all about it, with the result that I feel qualified to tip the bit of knowledge without which it will be a failure. It is essential to take up and replant the young growths which appear round the base of the old plant every spring. This is the only way to keep it, and its neglect means that we will lose it. It is worth the trouble, although I feel bound to say that its six or eight feet of height makes it unsuitable for every garden. But, be the garden big or be the garden small, wherever cut flowers are in request there should Monarch be. It is supreme among its relations for this purpose. The darkish disc and the big soft yellow incurving ray florets are just "it." I know no more delightful shade of yellow in any sunflower, and there is no better laster.—JOSEPH JACOB.

GENISTA ÆTNENSIS.

THE above illustration shows Genista ætnensis, which must be at least one hundred years old. The tree is over 20ft. high, and has a spread of some 30ft. and is growing at Howick, Northumberland. It is a wonderful sight when covered with blossom every August.—LADY MABEL GREY.

ROSES FOR A NEW GARDEN.

"WHAT kind of roses would you suggest for my new garden," was the pith of a question put to me a few weeks ago. On the face of it the enquiry was a very simple one, yet, on reflection, it was not so, for getting together a collection of roses is, in some respects (or should be), like purchasing pictures, inasmuch as we have to live with them, and they become companions over the years. In these circumstances, taste must predominate, and, therefore, we should choose with care. After all, roses in a garden serve a dual purpose; they bring in their train beauty and sweetness, and these are transmitted to the home through the summer and often far on into the autumn in the blooms we gather. If we have had previous experience, we shall assuredly linger over the names of hybrid teas, selecting those which have proved themselves generally serviceable, leaving out of our purview those which are comparatively unknown to us, or, in regard to which we have had no recommendation. It is not always advisable to be "carried away" with varieties we may have seen staged in superb form at some exhibition—varieties that are eulogised in the nurseryman's catalogue, which have probably been grown under special conditions for show purposes, and are beautiful as such, but are not suitable for general growing. We shall do well—nay we cannot go wrong—if we limit our selection to sorts of proved worth, in whatever class they may be found. Further than this, I would advocate confining the collection to fewer varieties, say three or four of each, rather than for the sake of being able to point to many trees with perhaps, only one or two of each. The reason for this is, that planted in groups of three or four of one variety, the effect in a garden is considerably enhanced, and, at the same time, it gives one greater latitude in carrying out any scheme of table decoration when we gather the blossoms. As an illustration—and I choose hybrid teas for this, I would be disposed, however many trees I purchased, to triplicate at least sorts like General McArthur, crimson; Ethel Somerset, shrimp pink; Ophelia, salmon flesh, shaded rose; Mrs. Henry Morse, bright rose; Mme. Abel Chatenay, carmine, shaded salmon; Golden Emblem, deep yellow.

These have proved their worth, and are possessed of delightful fragrance. Again, bearing in mind the service of roses in the home, I should be disposed to include at least a few singles, such as Isobel, carmine red; Mrs. Oakley Fisher, orange yellow; and Irish Beauty, white.

Although the section of hybrid perpetuals is a small one, it contains varieties having a long service, blossoms full and rich, and—most of them—sweetly scented withal. Such are old worthies like Mrs. John Laing Captain Hayward, Fisher Holmes and Mrs. R. G. Sharman Crawford. If Frau Karl Druschki—a recent introduction as compared with the aforementioned—only possessed fragrance, surely it would stand out as the very best all-round pure white, for it is a most continuous bloomer!

The modern garden, however, is incomplete if it does not possess climbers. It is so easy to overdo this in the construction of pergolas and arches as to injure, by taking away the light, other subjects in the borders underneath, which bring their quota of beauty and pleasure in their respective season. Rambler roses like Blush Rambler, Excelsa and Minnehaha, while exceedingly attractive in the time of blooming, are a fugitive race, and their beauty is soon over. I think this is becoming appreciated more, as one finds many of the climbing forms of Caroline Testout, Lady Ashtown and Richmond being planted where once members of the Wichuraiana held sway. In the matter of planting climbers, one should proceed with caution. In getting together a collection for a garden, however small, only those which merit purchase should be considered.

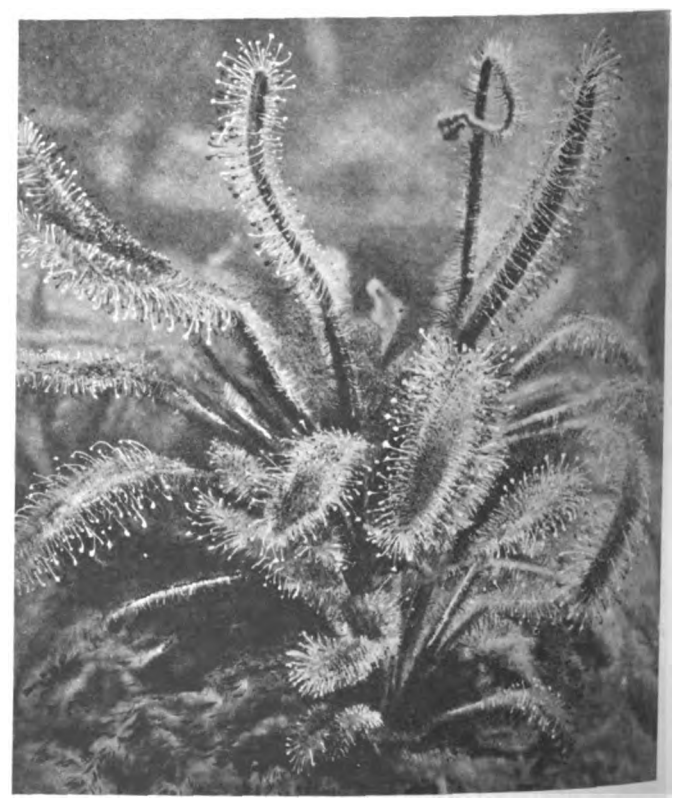
As we should select an artist's work—a picture which rivets our attention—or choose a piece of china with discrimination, so, in a measure, we should select our roses—by degrees, rather than become possessed of a collection of which we have little personal interest or knowledge.—W. LINDERS LEA.

CROCUS LONGIFLORUS VENUSTUS.

THIS little crocus, one of a number of charming seedlings for which we have to thank that lover of the genus, Mr. E. A. Bowles, is now in flower here (October 1st). The general colour of the flowers is a pale rosy mauve, the least glimmer of sun or accession of warmth bringing them fully out and disclosing the fascinating internal purple marking and feathering, well set off by the scarlet stigmata, while they exhale a sweet almond-like perfume. It is perfectly hardy and withal a strong and prolific plant. —EAST SUSSEX.

THE CAPE SUNDEW.

ALTHOUGH sundews are very interesting plants most of the species are somewhat insignificant in their habits of growth. The Cape sundew (Drosera capensis) is a really striking plant with comparatively large leaves. The flowers, which are of good size, are of a bright purple colour. The Cape sundew is of easy culture and will thrive in a compost of living sphagnum and a little peat. The leaves are amazingly good fly-catchers and, even in a greenhouse, will secure many insects.—S. LEONARD BASTIN.



DROSERA CAPENSIS, THE CAPE SUNDEW.

Digitized by Google

THE BEST EVERGREEN CHINESE BARBERRIES

THERE ARE FEW GENERA IN SUCH A STATE OF CONFUSION AS IS THE BERBERIS. IN THIS AND FURTHER ARTICLES MR. SCHNEIDER WILL CLEAR UP MANY DOUBTFUL POINTS.

AMONG Chinese berberis (exclusively of Mahonia) there are quite a number of evergreen species. Among them are a few that are quite hardy even on the Continent, and can be used there in about the same way as Berberis

ONE OF THE MOST HANDSOME OF BARBERRIES, B. GAGNEPAINII.

BERBERIS JULIANÆ.

stenophylla in England. None of them has, however, such beautiful flowers as this well known hybrid.

The first evergreen barberry that was sent from China to Europe was B. pruinosa, which Père Delavay, the great French explorer of the flora of some parts of Yunnan, sent to the Jardin des Plantes at Paris in 1894. I have often met with this species in the vicinity of the Likiang Range, where it flowers in the spring, often so early that the flowers are almost destroyed by the frost. In habit it is rather similar to the deciduous B. aristata, but the leaves of pruinosa are thick and leathery, and bluish white beneath. The flowers are of a clear yellow, but I have never seen them produced profusely. The berries are densely covered with a whitish bloom. I do not know of any large plants on the Continent, and I do not think that B. pruinosa is even as hardy there as B. verruculosa.

In 1898 another French missionary, Père Soulié, sent seeds of a different evergreen species, B. sanguinea, to Mr. Maurice L. de Vilmorin. This species flowered at Vilmorin's famous shrub collection at Les Barres for the first time in 1902. It comes from western Szechuan, and from what I have seen of it in European gardens, as well as at the Arnold Arboretum, I consider that it is quite hardy in a somewhat sheltered position. It has small, very stiff, linear leaves and greyish branchlets. The name sanguinea refers to the reddish colour of the outer sepals.

In the same year as B. sanguinea, or maybe even a year earlier, another species was sent from eastern Szechuan to Mr. de Vilmorin by Père Farges. This species had been detected by E. H. Parker in 1881, and Hance had given to it the name B. stenophylla, overlooking the fact that this name had already been used by Lindley for the hybrid mentioned above. In gardens this berberis was called B. levis, but so far as I know the true levis has not yet been introduced at all, unless Mr. Forrest sent some seeds home during one of his last expeditions. It is a rather local species from Yunnan, while B. Soulieana, as I called Hance's plant, seems to be widely distributed through Szechuan, Shensi and Kansu. It has once been confused with B. acuminata, another rare species from Yunnan that has not yet been introduced so far as I know, the B. acuminata of the gardens being mostly B. Veitchii, which is mentioned later. The true B. Julianæ at the first sight resembles a good deal B. Soulieana, and is as hardy as this fine species or may be even somewhat hardier. But so far, I have never seen large, well grown specimens, and I suppose B. Soulieana is inferior to B. Julianæ from a horticultural point of view.

In 1894, Père Farges sent another berberis to Vilmorin, which first was identified by Mr. Bois with the variety pallida of B. Wallichiana. Wallich's barberry is a Himalayan species, and extremely rare in cultivation. (I only once saw it in the Golden Gate Park at San Francisco.) But this name is mostly used for B. Hookeri. The Chinese plant has nothing to do with B. Wallichiana, and I, too, mistook it at first for a variety of B. Hookeri, calling it var. candidula on account of the snowy white under-surface of its leaves. After I had seen the plant in Vilmorin's collection I at once recognised it as a new species in no way connected with the real B. Hookeri, and it bears the name B. candidula. It is of an almost prostrate, dense, neat habit, and forms small slowly growing bushes best suited for the rock garden. In 1907 it was also found by Wilson in Hupeh, and he sent it to Veitch.

The first evergreen barberry that Mr. Wilson sent to Europe on his first journey in 1900 was B. Veitchii. It has only been found once by him in Hupeh. Veitch raised some plants from seeds, and distributed them under the name

Digitized by Google

B. acuminata already mentioned above. I have seen good plants of B. Veitchii in several gardens on the Continent, as well as in England. It is a very interesting hardy species, and forms loosely branched bushes with rather straight branches which are distinctly purplish when young. The long, narrow leaves are almost twice as broad and smoother and longer than those of B. Gagnepainii. The main feature is the rather large and pale yellow flowers standing in clusters of four to six or even eight.

In 1903 Wilson found another fine evergreen species in Szechuan. It has been figured in the *Botanical Magazine* on Plate 8185 as B. acuminata, which is, as explained above, quite a different plant. I named it B. Gagnepainii, and Mr. Bean is right in saying that it is one of the most promising of the barberries which Wilson introduced from China. Its habit and the leaves are shown in the accompanying illustration. The leaves are rather dull green, but the bright yellow flowers are not very showy. It looks its best in autumn when covered with its blue-black fruits. The bushes rarely grow more than 6ft. in height, and the greyish yellow branchlets are sometimes covered with tiny pustules similar to those observed on the branches of B. verruculosa, but by no means so significant. This species and B. Julianæ are, in my opinion, the two hardiest and probably the most ornamental of all barberries that we have received from China.

In 1903 Wilson found in the mountains of western Szechuan another very handsome barberry, of which he sent seeds to Veitch in 1904. It was B. verruculosa, a plant well marked by its verruculose branchlets, its small leaves with recurved margins and few spiny teeth being very shining and dark green above and more bluish green beneath. The flowers are of a beautiful golden yellow, and the fruits violet-black. It forms dense bushes 1–3ft. high. Unfortunately, on the Continent it is not so hardy as B. Gagnepainii or B. Julianæ, but it stands our winters well in a sheltered corner, where it cannot be injured by the sun and by cold winds in winter.

B. VERRUCULOSA, A NEAT-GROWING SHRUB

In 1907 Wilson was extremely lucky as regards berberis, and sent from Hupeh to the Arnold Arboretum no fewer than three fine evergreen species—B. Julianæ, B. Sargentiana and B. triacanthophora. The first one is the hardiest of all evergreen barberries I know of except, perhaps, B. buxifolia. B. Julianæ, as our picture shows, forms dense but graceful bushes up to 8ft. in height. The best plant I have seen on the Continent stands in the famous park of Prince Liechtenstein at Eisgrub, Moravia. It is not mentioned by Bean because at first in the Arnold Arboretum B. Sargentiana was believed to be the hardier species. Both look similar at first sight, but the young branchlets of B. Julianæ are pale greyish like those of sanguinea, while those of B. Sargentiana are reddish. The leaves of the latter are not quite as firm. The fruits of B. Sargentiana are almost black, and more broadly egg-shaped, not partly pruinose and ellipsoid as in B. Julianæ. The third species alluded to above, B. triacanthophora, is very different from the last two. It has been confused with B. sanguinea on account of its very narrow leaves, but it may easily be distinguished by its reddish and rounded branchlets, which are somewhat angular and greyish, as in B. sanguinea. The leaves of triacanthophora are less stiff, rather flexible and more finely serrate. According to Wilson, it reaches a height of 5ft., and the flowers are red outside as in B. sanguinea. According to my own observations, B. triacanthophora is not less hardy than B. Gagnepainii, but I have not yet seen large, vigorous plants.

Two very hardy species seem to be B. atrocarpa and B. Bergmanniæ, both found by Wilson and sent to the Arnold Arboretum from western Szechuan in 1908. B. atrocarpa was first taken for B. levis, and is mentioned by Bean under this name as a promising, vigorous evergreen. It is still rare even in English gardens, and it is similar to B. Soulieana, but well distinguished by its jet black, at first rather reddish fruits. Of B. Bergmanniæ the best plants I have seen are in the gardens of the Royal Horticultural Society at Wisley, where quite a number of evergreen as well as of deciduous species and forms of berberis may be met with. It has very firm and stiff leaves, resembling a good deal those of B. pruinosa, but are not distinctly pruinose beneath. Otherwise B. Bergmanniæ is more closely related to B. Julianæ, and apparently not less hardy and ornamental than this plant.

It would be very interesting to introduce B. levis and B. acuminata so as to be able to compare well grown plants with such species as B. Bergmanniæ, B. Veitchii and others mentioned above.

There are more evergreen barberries in China which we at present only know from herbarium specimens. They are all worthy of introduction, and I am sure that in years to come these evergreens will play a very important part in our gardens.

CAMILLO SCHNEIDER.

AUTUMN FLOWERS AT VINCENT SQUARE

THE display at the Royal Horticultural Society's Hall at Vincent Square on October 6th last, on the occasion of the ordinary fortnightly meeting of the Society, was indeed representative of the season of the year. In fact, the array of bright colour and bloom exceeded expectation. Michaelmas daisies predominated, while following close behind and providing a more vivid colour display were the roses, dahlias, chrysanthemums and gladioli. Berried and autumn tinted shrubs were present in variety and attracted much attention, while collections of fruit and vegetables were also staged and greatly appreciated.

Exhibits devoted to shrubs nearly always prove a source of unfailing interest. They show such an infinite variety in flower, fruit and foliage, and are so distinct in appearance and can be put to such an endless variety of purposes in the garden, that their popularity is not to be wondered at. Messrs. Waterer, Sons and Crisp's collection will do much to extend the popularity of shrubs in general and more especially of the genus berberis. What an infinite number of forms this family contains. In Messrs. Waterer's collection such species as B. Stapfiana, concinna, Coryi, Gagnepainii and aggregata were present and provided a brilliant display of scarlet and green. Another striking shrub which is excellent in fruit was Euonymus vedoensis. This looked well backed by the brilliantly autumn-tinted Rhus typhina laciniata and Liquidambar styraciflora. Pernettya mucronata, Dabœcia polifolia and others of the heath family, such as Erica Searlii, contributed to a very fine collection, which included in addition several handsome

Digitized by Google

specimens of conifers, embracing a Taxodium sempervirens with light glaucous foliage, and one or two interesting junipers from Asia.

Messrs. Cheals also staged a fine collection, which included Desmodium penduliflorum in full flower. An interesting trio of snowberries were shown, embracing SS. racemosus, lævigatus and mollis. The differences were most marked. A dash of bright colour was supplied by the shining scarlet berries of Ilex pyramidalis; while autumn tints were provided by the inclusion of Kœlreuteria paniculata, Cornus sibirica, Acer japonicum laciniatus and Pyrus discolor. This year especially, autumn colouring in fruit, foliage and stem is exceedingly good, and is probably in no small measure due to the open weather which we are experiencing and to the fact that the wood is having a proper chance to ripen thoroughly.

Autumn and asters are upon us, and this Show came at a date when Michaelmas daisies were at perfection. On examining the stands one was struck by the considerable variation which the same variety showed when grown by different people. Snowdrift, for instance, was only moderate in size and form when shown by some firms, whereas on the stand of Mr. T. Bones it could be described as one of the best of whites. That intense blue aster, Ultramarine of the Amellus section, seemed to vary with different treatment and soil. King George and the Ballard family, Anita, Margaret, Percy, Rachael and Ethel, were everywhere. Mr. Ernest Ballard's stand was a mass of them. Margaret Ballard is a lovely variety with large semi-double flowers of bright rosy mauve. Powder Puff was one of the newest of Mr. Ballard's asters. It is a dainty arrival, attractive in colour and form. A variety such as Little Boy Blue will be hard to beat and, together with Pink Lady forms the perfect pair of dwarf daisies. Queen of Colwall, October Dawn, Duchess and Freedom, on Mr. Ballard's stand, could not be passed by unnoticed.

Mr. H. J. Jones made an effective stand with bold groups of asters and helianthus, the bright yellow of the latter forming an attractive contrast with the mauve and blue asters. What a fine Amellus variety is Rudolf Goethe with its huge lavender blue flowers. Mr. Jones had some excellent sprays of it. Beauty of Colwall, Aldenham Pink, Nancy Ballard, Maid of Athens and Countess were some of the most striking of the Novi Belgii section shown by Mr. Jones.

Messrs. Waterers had the only ground group of Michaelmas daisies. Dick Ballard was, perhaps, the most outstanding variety; but it was hard to choose the best from among a group of such well known specimens. Namur had pretty soft pink flowers, Ethel Ballard a well shaped spike, and Mons was another single of the rosy tone. Beauty of Ronsdorf was a fine Amellus.

Barr's Pink, on the stand of its raisers, quite outshone any other variety. Its large bright rosy pink flowers are semi-double and well set off by the conspicuous centres of gold and bronze. Many other good varieties, such as Dick Ballard, Mons, Heather Glow and the Amellus variety Mrs. Perry, were also shown by Messrs. Barr and Sons.

Mr. W. Wells, jun., had a fine collection. Robinson, V.C., October Dawn with its mass of lilac mauve flowers; Grace Sweet; a distinct dark blue; Brightest and Best; and Blue Gem were shown by this firm. Mr. T. Bones had several noteworthy varieties, one being Perky, an attractive addition to the Novi Belgii section. It is dwarf in habit and compact, and the colour is pale rose. Kate Bloomfield, one of the best of the Novæ-Angliæ section, was also shown; and Mother-o'-Pearl, a soft mauve single, attracted much attention.

The Orpington Nurseries had a varied collection. Cloudy Blue, with its pale, semi-double flowers of lavender blue, was among them. Michaelmas daisies of all types were well shown by Messrs. Rich and Co., Messrs. B. Ladhams and Mr. Marcham. Mr. F. K. Wood had several good asters of the Amellus section, such as King George and Rubellus. The strange semi-double opal-grey flowers of the variety Grey Lady were shown by Messrs. Rich and Co. The ray florets of this variety are very long and loosely arranged. Among kniphofias and various hardy plants Mr. Amos Perry staged some fine asters, such as Rachael Ballard, Royal Blue and Ethel Ballard, typical members of the valuable family of Michaelmas daisies.

The chrysanthemums were a strong feature of the Show. Mr. J. W. Forsyth of Putteridge staged a choice collection of varieties, all grown in the open without protection. All the blooms were in excellent condition and provided a bright colour scheme. Included in the exhibit were such sorts as Almirante, of chestnut crimson colour; Bronze Normandie; Cream Masse; Pink Delight, with large flowers of a clear pink tone; and October Yellow. The flowers were all carried on stems about 2ft. high and appeared very floriferous.

A very fine exhibit of double and single sorts was also staged by Messrs. Keith Luxford, whose name needs no introduction to chrysanthemum lovers. Included on their stand was the excellent white Framfield E. White; Goldfinder, of a rich golden yellow; J. Bannister, lemon yellow; Pink Profusion; and Uxbridge Pink. On Mr. Yandell's stand such varieties as Waterwitch, which is a very fine white single; Red Almirante; Salmon Profusion; and Knaresboro' Yellow were shown to full advantage and all looked in good condition.

For this time of the year, the roses which were on show were really in excellent condition. Each exhibit was as good as its neighbours. All the leading rose growers staged fine collections, including all the well known varieties. The colours of the blooms were very fine, while the petals of the individual flowers showed little or no sign of damage by early frosts. The following firms were exhibiting roses: Messrs. Easleas; Messrs. D. Prior; Messrs. Pemberton; Messrs. Harkness; Messrs. B. R. Cant; Mr. Elisha Hicks; Mr. George Prince; and Messrs. Chaplin Brothers.

Only a few alpines were shown. Messrs. Maxwell and Beale exhibited their new seedling of Erica vagans, Mrs. D. F. Maxwell, with the older and paler variety, St. Keverne. Both have the same quality of brownish pink without any tinge of purple that is almost peculiar to these heaths, and they go very well together. The fine old pink Donizetti, a curious dull red with a darker centre, was still blooming freely; beside it was the even older double Colchicum autumnale, rather ragged and untidy in its excessive doubleness.

Messrs. F. G. Wood made a charming little autumn garden of dwarf conifers and late blooming alpines; Colchicum byzantinum, thrusting up its clear lavender pink goblets through the grey green sprays of Juniperus tamariscifolia; Potentilla fruticosa Farreri lighting up with its clear buttercup yellow the sombre purple of Pentstemon Kellermanii; and Chelone Lyoni, with odd turtle's head flowers of pure pale pink standing out clearly against a background of grey rock were all shown.

A really wonderful collection of vegetables, which was awarded a gold medal, was staged by the Hon. Vicary Gibbs. One always expects from Aldenham only the very highest quality, but this time Mr. Edwin Beckett excelled even himself. The vegetables were not only excellently grown and staged, but the large variety shown made the exhibit one of the best of its type ever staged. Messrs. Dobbie had an interesting collection of many kinds of potatoes, including disease-resistant varieties.

Dahlias, carnations and hardy border flowers were also shown, and the following had interesting collections:

Carnations.—Messrs. Allwood Brothers, C. Engelmann and Stuart Low and Co.

Dahlias.—Messrs. J. Cheal and Sons, William Cutbush, James Riding, Charles Turner and J. T. West.

Gladioli.—Messrs. Dobbie and Co. and Mr. Alfred Edwards.

Hardy Flowers.—Messrs. T. Carlile, K. and E. Hopkins, B. Ladhams, H. Marcham, A. Perry, M. Prichard and W. Wells, jun.

Violets.—Misses Allen-Brown, Mr. J. J. Kettle and Mr. Baldwin Pinney.

NEW AND RARE PLANTS.

AWARDS OF MERIT.

LIATRIS SCARIOSA ALBA.—As the name indicates, this is a white-flowered form of this hardy North American perennial. The numerous heads of flowers are carried in a fairly loose spike and differ from the type species in colour and in being slightly larger. It should prove a useful addition to the hardy wild flower border. Shown by Mr. Amos Perry.

CHRYSANTHEMUM ENCHANTRESS.—A good double variety, carrying flowers of medium size. The petals of the blooms are of a clear rose pink colour and have that silken sheen which is so often lacking in many pink sorts. Shown by Mr. Thomas Bones, Cheshunt.

CHRYSANTHEMUM CRANFORD CREAM.—This variety is a fine addition to our early double flowering sorts. The blooms are of medium size and soft cream coloured, merging into a light cream-yellow centre. Shown by Mr. W. Roots.

NÆGELIA WALMSGATE BEAUTY.—An exceedingly graceful representative of the Gesnerad family, with all its attendant characteristics. The soft velvety leaves are more or less cordate in shape. The flowers are borne in a loose terminal cluster and are whitish pink in colour suffused with yellow in the throat, which is spotted. These dangle gracefully on long petioles from the upright stem. This variety makes a fine ornamental pot plant for a warm house. Shown by the Director of the Royal Botanic Gardens, Kew.

ORCHIDS.

LÆLIO-CATTLEYA QUEEN MARY VAR FULGENS.—One of the finest forms of this hybrid between L.-C. Lustre and C. Peetersii. The spike bore three very large flowers, having the sepals and the broadly developed petals of a uniform rosy mauve colour. The expansive labellum ruby crimson, except for a small yellowish area on the inner side of each lateral lobe. This hybrid was originally named in honour of Queen Mary's visit to Westonbirt. First-class certificate. Shown by Lieutenant-Colonel Sir George Holford, K.C.V.O., Westonbirt, Tetbury, Glos. (gardener, Mr. H. G. Alexander).

LÆLIO-CATTLEYA PANDORA (C. Fabia × L.-C. Marmion).—A beautiful hybrid with a single large flower of bright flesh colour in the sepals and petals, the labellum ruby-coloured, the lateral lobes having a golden area in the centre, while the extreme margin is rose-tinted. A distinct break away from the usual colouring. Award of merit. Shown by Messrs. Cowan and Co., Southgate, N.

CATTLEYA BELLONA VAR. ST. ALBANS (C. Dowiana × C. Maggie Raphael).—An elegant result in which the spike carried four flowers having greenish yellow sepals, cream-coloured petals and the labellum ruby-crimson over its entire area, with some gold veining. The column is cream-coloured. Award of merit. Shown by Messrs. Sanders, St. Albans.

CORRESPONDENCE

CYTISUS SCOPARIUS ANDREANUS.

SIR,—I have here an old shrub of Cytisus scoparius Andreanus of considerable size, and I should be glad to hear if any of your readers know of a larger. The circumference of its trunk a few inches from the ground at the smallest part before it begins to branch is 27ins. It covers an area with a circumference of about 50ft., the whole plant being perfectly healthy and covered with blossom every year.—LADY GEORGE CAMPBELL, *Argyll.*

ROSES ON THEIR OWN ROOTS.

SIR,—Having been very successful in striking roses on their own roots, I beg to corroborate the practical hints given concerning this subject by Mr. T. W. Briscoe in your issue of September 26th. The only point of difference in treatment between myself and Mr. Briscoe is his choice of a partially shaded position, whereas I have always put rose cuttings in an open unshaded place. Evidently this is an item of practice that need not be unduly emphasised one way or the other.

My experience leads me to add that acknowledged weakly growing varieties are not worth troubling with unless the soil is light and the position warm where the plants would afterwards have to grow. Hybrid perpetuals, hybrid teas and teas I have found to root quite well in the open ground—though I admit the growth of pure tea varieties is freer and stronger in a frame than when managed entirely out of doors. As adding interest to this subject the accompanying illustration will not be out of place as it shows a bed of Caroline Testout well established on its own roots.—C. T., *Ampthill Park.*

ROSE CAROLINE TESTOUT ON ITS OWN ROOTS.

THALICTRUM DIPTEROCARPUM.

SIR,—Do you know what you have done? You have made me get out of bed at three in the morning to fetch my writing pad, in order to write a short note about the delicate charm of Thalictrum dipterocarpum when grown in 5in. or 6in. pots in a cold house. It was in war-time. I had raised about a dozen and a half plants from seed, and, reading about their doubtful hardiness, I put them in pots. As everyone knows, heat had to be severely economised then. They got frozen solid, and I thought it would be all over with them. But no. The pots thawed in due course, and then the dipterocarpums went ahead as if nothing untoward had happened, and in due time produced a crop of the most lovely pale mauve fairy parachutes that to me, at any rate, were far more fascinating than the rosy lilac ones which "R. H." (pages 540–541) and others see out of doors in borders and in wild gardens. This is the peg: I want to hang something on it. I do appreciate the more human touch in THE GARDEN, and I feel there will be many another who will do so too. Often have the garden giants of olden days expressed to me their regrets at the comparative absence of the personal "pars" which were such a feature of the paper in the far-off days when Robinson edited and Moon drew those fine coloured plates. Mr. Editor, go on as you have begun, and you will get lots of people out of bed to jot down something that suddenly occurs to them and which they think will be of interest to their fellows, if they feel it has a chance of seeing daylight in your pages. A cat may look at a king. Doubtless some of these contributions will bear something of a resemblance to the cat. But have you ever heard that either king or cat were any the worse for the proceeding? I must produce my Van Oosten chestnut. (Kind readers, forgive me doing so, but it just hits off my feelings about having these notes and "pars" in our paper. Some day we may be able to stand in our gardens and broadcast our ideas and thoughts to all and sundry; but until then let us be thankful that we have a paper and an Editor who—for the time being, at any rate—are our *Deus ex machina.*)

"If the Tulips should be made common the civilest Dealing that is in the World would thereby be taken away from Men, and they would be deprived of the sweetest Communication that is among honest Men. How many pleasant Visits? How many friendly Conversations? And how many solid Discourings? It is a very pleasant Entertainment of our thoughts to be thus busie with the Contemplation of Flowers." (*The Dutch Gardener.*)—JOSEPH JACOB.

GARDENING IN EAST ANGLIA.

SIR,—Having read with much interest Sir Herbert Maxwell's note on "Gardening in the West of Scotland" in THE GARDEN of September 5th, I want to put in, once again, a plea for East Anglia, though feeling that so humble an amateur as I should hardly throw down even the most Liliputian of gauntlets to such an authority as Sir Herbert. But, being a dweller, and gardener in East Anglia—and in that Cinderella of counties, Essex—I want to query the statement that the "British climate varies far more according to longitude than latitude." In many cases this may be so, but I have found that at my own home, Thorpe-le-Soken, we have been able to grow a large number of the tender shrubs and plants that are supposed to be limited to Cornish gardens. For instance, we have two Eucalyptus Globulus trees beside a pond, that are "forest trees," and which in 1914 bloomed and seeded themselves in half a dozen places. Near Brightlingsea, high up, and exposed to every gale from the North Sea, there are a large number of eucalyptus—Gunnii, I think, so far as I remember at the moment—thriving in the hedgerows and of considerable age, having been planted there as seedlings by an inhabitant who loved their evergreen beauty.

Besides E. Globulus in my own garden, we have been most successful with the more tender olearias and veronicas, procured originally from the Cornish garden of my brother-in-law, the late John Boscawen.

Clianthus puniceus thrives with us against a sheltered wall, and Abutilon vitifolium has made two fine bushes at the back of a border in quite an exposed situation. In addition to these specimens, my gardener has, during my absence in Canada, succeeded admirably with various Australian shrubs that, so far, I have not seen, and this has encouraged me to resolve that when I return home next year I shall make many more experiments with those tender plants which are supposed to grow nowhere except in Cornwall.

I rather fancy that the explanation of this ability to "do" the tender plants in our part of Essex is due to the fact that, being near the sea, though some two miles inland, we get the humidity of the salt air that softens down the rigours of frosts (of which we really have very few), and also that our summers have many very fiercely hot days of prolonged sun that ripen the wood swiftly and thoroughly. I should be much interested to hear if others among your readers who garden in East Anglia have had the same experience with regard to tender plants.—EVELYN BYNG OF VIMY, *Government House, Ottawa.*

POTENTILLA FRUTICOSA.

SIR,—Your correspondent "H. A. G." describes a number of shrubby potentillas, some of which he thinks must be wrongly named.

P. Veitchii he speaks of as sulphur. I had this from Veitch when it was first introduced: the true Veitchii is a dwarf grower with pure white flowers. P. Vilmoriniana sounds true to name: the leaves are of a beautiful silvery colour. P. Friedrichseni is a garden hybrid, raised by Späth of Berlin, the parents being P. fruticosa and P. davurica. This is a good deal deeper in colour than P. Vilmoriniana; but there is a pale form of it, P. Friedrichseni ochroleuca, which I have had from Messrs. Smith of Newry. The leaves of Friedrichseni are bright green. I know few shrubs more valuable than this for continuous flowering: and pale yellow is a colour of which we have too little.

As for Farrer's potentillas, I imagine that it will be difficult to sort these out as named species. Farrer found them, did he not, growing all mixed up as scrub on the hillside? If I remember rightly, he speaks of them in "On the Eaves of the World" as being probably natural hybrids between fruticosa and davurica. In his own collection of them every shade from the deep yellow of fruticosa to the white of davurica was represented; but I think none had a leaf as large as that of Friedrichseni. Nearly all these forms of Farrer's importation are delightful garden plants.—W. ARNOLD-FORSTER.

GARDEN TECHNIQUE

Notes on the Technical Side of the Garden and the Cultivation of Plants

LILIUM LONGIFLORUM GIGANTEUM.

AT present in the garden this species is providing a gorgeous display and a striking contrast. Situated, as it is, at the back of the glowing flowers of Coltness Gem dahlias. The display of this novel combination of lilies and dahlias has lasted throughout September and will continue in October if severe frosts are absent.

The cultural details in connection with this most beautiful autumn-flowering lily are such that anyone can follow with every hope of success. Good bulbs were procured by us in the spring and set out early in April, 3ins. to 4ins. deep (measurement take from tip of bulb to surface of soil), in the corner beds of our flower garden. The soil was in fine condition for planting at that time and had been manured and dug exactly one month previous to the date of planting. The stems of this beautiful lily attain a little over 2ft. in height and from two to four flowers are borne by each stem. R. Wallace says of this lily, "a grand plant of very free growth; the flowers are large and well formed, of great substance and purity, lasting a very long time when cut."

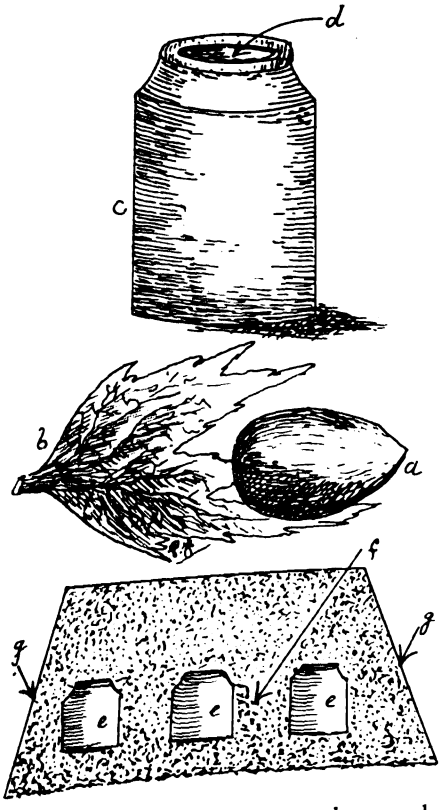
On the same day bulbs of Lilium auratum platyphyllum were set out in the beds, but farther back. This is a much taller-growing lily and later in flowering; it has also grown well and is now, October 1st, furnished with flowers, which, however, are not quite opened, but should provide a lily display throughout the present month.—D. ARMSTRONG.

THE TREATMENT OF BOUGAINVILLEA, PLUMBAGO AND SIMILAR GREENHOUSE ROOF PLANTS

THESE hard-wooded plants, jasminum and heliotrope, well treated in regard to soil, training and pruning, create in lofty structures quite a sub-tropical appearance. They may be grown in small houses with good effect, too. One frequently sees odd plants of some of them blocking up a corner or a roof of a greenhouse; these specimens form a mass of shoots, some of the latter bearing a few puny flowers. This is not the right way to grow the plants. Whether trained to supporting pillars or under the roof glass they should be treated—unless in exceptional circumstances — as cordons similar to grape vine rods. Neglected plants may, during this autumn, be pruned severely and brought into good shape. Young ones, to be planted now, should possess a single long rod or stem, not one that branches much. In every case they should not be nearer to the roof glass than 18ins., 2ft. being better if there is sufficient space. When the flowers have faded, or most of them, cut back all side shoots to within 4ins. of their base. Having removed so much top growth, less water will be needed at the roots. Indeed, till early next February the soil should be kept on the dry side. About the middle of January again prune back the spurs to within 2ins. of their base. Soon after doing this thoroughly soak the border with clear water. Thin out the resultant new shoots and allow some of those retained to hang gracefully from the roof. When in flower they will look charming.

NUTS AND FRUIT

NATURALLY. nuts, when stored, form and not like all other stored. a bush in the hedge, generally keep well. We may find them in the grass or under the leaves on the hedge bank in the depth of winter, but the kernels are plump and sound, crisp and sweet to eat. Those badly stored artificially are often found to be shrivelled and of a musty flavour. So, to be able to store our harvest of nuts successfully we must imitate nature. In the accompanying sketch we see at *a*, a filbert freely parted from the "husk," *b*. All nuts, including walnuts, should be free of the outer "husk" spread out in a cool draughty place, not exposed to the sun and rain, for a few hours to dry. One turning will be sufficient; then pack them firmly in jars, *c*, and use a good cork, *d*. Store the filled jars, *e*, in dry sand, *f*, in a cellar for choice. The sides of the heap, *g*, *g*, should be free from outside walls. In this position the nuts will remain sound for a long time. Store in a body of sand, not on the floor itself, and then cover with sand.



Medlars should be stored eye downwards, on a thin layer of sand on a shelf in the fruit room or in a dry cellar. Quinces store as pears in the driest part of the store, and apples in the coolest.

BULBS IN POTS AND BOXES.

THE management of bulbs in pots and boxes just when they begin to grow is a very important point in their general treatment. Some cultivators place empty inverted flower-pots on the pots containing the bulbs and then cover all with ashes or sand. The empty pots prevent the covering ashes from pressing unduly on the new growths and, perhaps, causing loss of flower spike or malformation. Where only a few bulbs are grown this plan of covering does not entail much labour, and, furthermore, it is necessary, from time to time, to examine the progress of the new shoots to enable the cultivator to regulate the growths by leaving the bulbs longer under the covering material or removing them to a cold frame. When the bulbs are covered with sand or ashes these must be very carefully moved to one side when the bulbs are being examined from time to time, or the tender embryo flower stem may be broken. In the case of tulips and narcissus the new shoots should have grown about 3ins. in length when the pots are removed from the covering material; the embryo flower stems will not be visible. In the case of hyacinths, the embryo flower stem will be visible at the stage when the new growth is 3ins. long. Remove the pots to a bed of ashes in a cold frame, and immediately darken the frame by placing mats or sacks or litter on the glass and keep the frame closed. The after-treatment consists of the gradual exposure to light and air and careful watering and feeding.

THE LILY OF THE VALLEY.

I DO not know anyone who dislikes the lily of the valley, although a few persons in every county may do so. Now, simple as this flower appears to be, the plant is most difficult to grow in many gardens, whereas in others it grows like a weed. For very many years I grew a quarter of an acre of the lily of the valley, not in one place but in several positions in the garden; these faced east, south and west respectively. Not any faced due north. In one garden the plants would not thrive at all, so a bed was prepared on the north side of a wall, and here the plants succeeded well. This was in a Lancashire garden; the large area was in a Hampshire garden, and yet in another Hampshire garden the lily could not be successfully grown except in a border facing north-east. I experimented with various top-dressing materials in the case of the larger area, where the roots permeated the soil under the pathways and grew there luxuriantly. In the woods where this lily grows naturally—to my knowledge in the Eastern Counties, in Cumberland and in Hampshire—natural top-dressing materials are available from the trees; in Hampshire may be seen beds covered with pine needles. The lilies were the finest I have seen and grown in peat and sand. Pure loam I found to be the worst, and leaf-soil and sandy loam the best, top-dressing material. Rotted manure was bad except when applied in small quantities. When planting new beds or renovating old ones the crowns should be graded and not planted nearer together than 9ins., to allow for increase; overcrowding is wrong.—G. GARNER.

HEAVY TOMATO CROPS.

IN this country tomatoes must be beautifully round, fine in texture and not too large, otherwise they are quickly discarded and pass out of favour. Abroad, however, and particularly in those parts of the world where the tomato is a field crop, this is not the case, and often one finds the favourite to be a variety which bears very heavy crops of huge, coarse (in our opinion), and badly-shaped fruits. For two years I have grown one of these kinds, ponderosa, a variety which is fairly common in America, Italy and Japan. Well grown plants bear much heavier crops than the favourites of our gardens and the fruits are so large that one to the pound is comparatively common. The fruits are almost invariably badly shaped, something like the original varieties of "Love-apple" grown here; the flavour is not at all bad and in the cooked condition it is quite impossible to discriminate between the home and the ponderosa. I can only add in conclusion that I intend growing a few plants every year—so that my final opinion is not entirely against it.—CLYDESDALE.

BOOK REVIEW.

WITHIN recent years the nomenclature of probably the greatest economic group of insects has undergone almost revolutionary changes, and horticulturists and agriculturists alike will welcome the volume, "A List of British Aphides," by J. Davidson, B.Sc., F.L.S. (Longman's, Green and Co., Paternoster Row, E.C.4, price 12s. 6d.), which has been recently published.

The book, as the author states, is intended only as a reference book and as an aid to collectors in the field in the identification of species. From that viewpoint it serves an exceedingly useful purpose and will be found to be a valuable guide.

Of the four sections into which the book is divided, the first deals with species found and recorded in Great Britain, together with a list of their host plants and their distribution in area. In Section II is an alphabetical list of genera found in this country with their synonyms, and critical notes: while Section III contains a list of food plants on which aphides have been found. An exceedingly useful, although incomplete, bibliography ends the monograph, which, from the scientific standpoint, is an important contribution to entomological literature. It is, however, beyond the scope of the practical gardener, unless he be a keen entomologist.

The general arrangement is good and the text is most clearly printed. Save for a few errors in plant names, which are rather glaring, the volume is remarkably free from those blemishes which result from careless proof reading. G. C. T.

A Rose Competition in Scotland.—It may be recalled that last year THE GARDEN held a competition to decide by the popular vote of its readers, what, in their opinion, were the best six hybrid tea roses in cultivation. The competition created widespread interest at the time, and it is gratifying to see the success that has attended a competition on similar lines run by the *Daily Record and Mail* of Glasgow. In this case the question set to the competitors was the choice of twelve representative varieties which they considered best for garden decoration. Four hundred and three lists were received from all parts of Scotland, indicating the enthusiasm of amateurs in rose cultivation. The best twelve roses resulting from the plebiscite vote were as follows: Frau Karl Druschki, Caroline Testout, Mme. Edouard Herriot, General McArthur, Ophelia, Golden Emblem, Hugh Dickson, Lady Pirrie, Mme. Abel Chatenay, Mrs. Henry Morse, Los Angeles, Betty Uprichard. It will be seen that this list includes the six varieties which readers of THE GARDEN considered as the elect. This serves to show that the popularity of such sorts as General McArthur and Ophelia is as widespread in Scotland as elsewhere. We extend our congratulations to the *Daily Record and Mail* on the success of its effort, which will give a stimulus to rose cultivation throughout Scotland.

NEW CHRYSANTHEMUMS.

THE Floral Committee of the National Chrysanthemum Society met at the Royal Horticultural Hall, Westminster, on October 4th last, and made the following awards to novelties:

BRIGHTNESS.—A beautiful Japanese variety with flowers rather larger than is usual with the early-flowering varieties. The flowers are a bright crimson colour lightly touched with maroon. First-class certificate. Shown by Mr. H. Woolman.

CRANFORD CREAM.—This seems to be one of the most valuable early-flowering new chrysanthemums of the season. It is a very free-flowering variety, producing plenty of sprays of substantial flowers of medium size and pale creamy primrose colour deepening in the centre. First-class certificate. Shown by Mr. W. Roots.

CRANFORD RED.—A showy variety of reddish chestnut colouring, passing to reddish orange at maturity. It makes plenty of sprays of narrow petalled flowers. Commended. Shown by Mr. W. Roots.

NANCY THOMAS.—A pretty free-flowering variety for the border. The flowers are of a reddish terra-cotta shade and are freely produced. The plants are of very dwarf and compact habit. Commended. Shown by Mr. H. Woolman.

TRADE NOTES

"Windolite," the Unbreakable Substitute for Glass.—In recent months, much prominence has been given to a composition known as "Windolite," an excellent substitute for glass, and concerning which we have recently received some interesting information regarding the various uses to which it can be put. It consists of a transparent composition reinforced with fine wire netting, and is flexible and unbreakable. It can be employed in the construction of garden frames, hand lights, farm buildings, factories, etc., and the importance of the material lies in the fact that it admits ultra-violet rays which are excluded by glass. Experiments with "Windolite" are being carried out by several well known people in both the medical and horticultural worlds, and it has been found that the plant, like the animal, is greatly benefited by ultra-violet rays. "Windolite" is a washable material which admits all light and excludes wet and cold. It is light, can easily be cut and fixed, and from it cloches, hand lights and shelters made for many types of plants. "Windolite is said to prevent plants from being "drawn" or scorched, as they are liable to be under glass. Instructions for making simple plant protectors and cloches are given in the pamphlets supplied by the firm of manufacturers.

The Briton Chemical Products.—Of the several Briton Chemical Products I have, during the past few months, had experience of the following:

THE "FERRY" INSECTICIDE.—This has proved to be a splendid plant wash—easy to apply, not unpleasant to use and very effective against rust, the milder mildew form of it, and other fungoids. It is also efficacious against thrips, aphides and red spider, which are so troublesome on plants during sudden changes from hot to cold temperatures and *vice versa*.

THE "FERRY" GARDEN MANURE.—This is claimed to be a most useful manure for general purposes. I applied some to growing crops of vegetables and also to pot plants, chiefly chrysanthemums, and found that the pot plants benefited quickly, as their roots were confined to a small space. In the open border stronger doses can be applied, and though not quite as rapid in action as in the case of the pot plants, the resultant benefit was lasting.

THE "FERRY" ANTISEPTIC.—This, also, was well tested and proved very safe and cleansing in all places where it is necessary to use regularly a reliable disinfectant. As an antiseptic it was used on the arm of a lady who was stung by an insect. A swelling and running eczema developed and, after various remedies had been tried without avail, the "Ferry" Antiseptic was applied at full strength, bathing the part and tying on a swab soaked in the solution. In three days the running sore had stopped and clean skin formed; in a short time no trace of the trouble was to be seen. A very important point in using these products, I find, is the careful application according to the instructions. G. G.

FARRER'S WORD PAINTING

FIVE years ago, on October 17th, 1920, Reginald Farrer died at Nyitadi on the Burmese-Chinese frontier. There is no need to remind gardeners of the debt they owe him, for his personality lives in his writings, so vividly that no one who has ever caught the Farrer tang can refrain from reading and re-reading his books. It is true that many of them cannot be read through from the first to the last page over and over again—"The Rainbow Bridge" and "On the Eaves of the World" are exceptions, for they are great travel books as well as works on the flora of an out of the way corner of the world—but one can spend endless half-hours of enjoyment in dipping into others here and there.

Like in most interesting authors, his style was argumentative. He loved prodding people by means of his own vivid perception and vision, and he always wrote with an assurance that at times must gall some of his readers. This has given rise to the accusation one sometimes hears, that he weaved a spell over some plants that were unworthy of his pæans of praise.

It has also been suggested that he allowed his pen to run away with him and over-coloured some of his descriptions in order to force into prominence plants which he knew in his own perception were not so marvellous as he made them out to be. That is not true. He was always sincere. He had violent likes and dislikes, and some of his tastes in plants were unusual. What he did was to realise the power of his own pen and so bring into the limelight plants which he thought were neglected. One had to know him well before one realised the fire of his enthusiasm, which came more to the surface when he was writing than when he was talking. Sometimes the exuberance of expression that bursts forth in his books is almost embarrassing.

Here are two examples of his descriptions: one plant I have not seen; the other I know well and was present at its discovery. I re-read the other day in "My Rock Garden" his description of his long hunt for Eritrichium nanum above Zermatt. Has ever a plant had such a wealth of rhetoric poured upon it? One follows him up the gullies breathlessly, shares all his doubts as to its existence. "Already I am ing to feel rather tremulous. For we are very high up he crown of the pass is straight above our heads, dred feet. Somewhere in that four or five diant triumph or blank disappointment." entence until one is terrified of an his skill carries him past the make sure of the bliss no delusion, no silly Myosotis—it is Eritrichium itself. A calm glory of destiny fulfilled descends upon me." He then goes on to describe the plant and the description includes a masterpiece of word painting of colour: "I find that in Eritrichium a dash of Chinese white is mixed with the azure, and thus the softer tone is produced; there is also—and now I must be read with caution—the minutest, minutest touch of crimson,—oh, so little that the very suggestion seems ridiculous, and yet the cobalt-laden brush, after a lick of white, must make the merest feinting flirt across the cake of crimson, if the rich, clear, gentle, perfect blue of the flower is to be finally divorced from any suspicion of yellow. For, into nearly all the azure flowers we know, a suspicion of yellow enters, and leaves a tang of green; only Eritrichium is perfect and undefiled in its tone." And so on. I have never been fortunate enough to see this plant in its full glory, but I am so certain of Farrer's sincerity that I am not at all sure that I do not prefer to look at it through Farrer's eyes than through my own. I probably get more enjoyment from reading, at my own fireside, this chapter, which was written months after the event, than if I toiled up those hot gullies to see it for myself. It may be partly laziness, but I have a vast admiration for the way in which he piles Pelion on Ossa for the sake of a carpet plant, and leaves me satisfied at the end.

Another picture: our first view of Nomocharis pardanthina on Hpimaw Hill. We rounded a corner which we had seen many times before but had not visited for a month, and came unexpectedly on what he called "sweeps of ten thousing times ten thousing all over the alpine meadows wherever there are any!" My own feelings do not matter, for I am writing about Farrer; but I distinctly remember that we kept deathly silent for probably five minutes. This may partly have been because it was so unexpected, but he said very little for the rest of the day. His feelings were slowly incubating, and only on the next day did he start to burst into song. It was one of the few individual flowers that he mentioned in his letters home. Thus, in one of his articles in the *Gardeners' Chronicle* his feelings began to take shape, and he wrote: "How shall I describe it, for the benefit of those who have only seen its lovely flowers drooping lonely in a pot at a show? It is most like some hybrid of a minor lily with Odontoglossum Rossii, combining the perverse and sinister spottings of the one with the frank and graceful loveliness of the other, alike in proud, meek port and delicacy of shell-pink colouring. And when you see it on the open high alpine grass-slopes of Hpimaw pass nodding down at you with myriads of wide-open, dark-eyed faces, in every shade of

Digitized by Google

pale rose and every degree of freckling, there is nothing very much left for you to look at on Hpimaw pass." What would he have said in a book? And yet he could not have said too much, for I was there and saw the sight for myself.

In his account of eritrichium he said that he found it when climbing with a party of friends, probably either Mr. Bowles or Mr. Clarence Elliott was with him. It would be interesting to know if the same process took place on that occasion.

Beauty is not the same to all eyes, but I do not think that even this criticism of over-description can be laid at Farrer's door. He was sincere in describing a plant as he saw it.

E. H. M. C.

SOME GARDEN DESIGNS—I

A RECTANGULAR LAY-OUT SUITABLE FOR COUNTRY OR SUBURBAN NEIGHBOURHOODS.

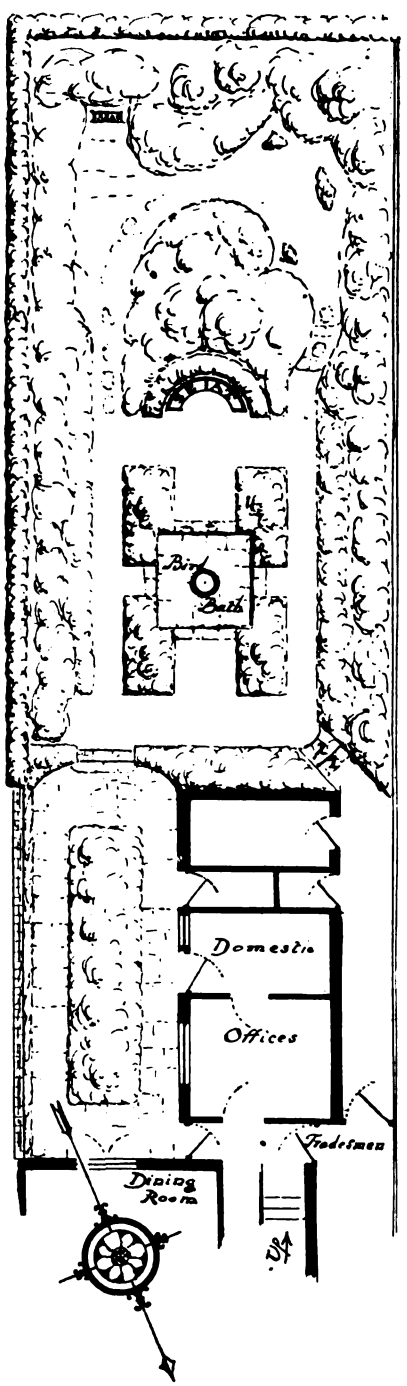
ON the artistic principle that one should work always from the simple to the complex, the lay-out of a small rectangular garden-plot, such as one finds in the suburbs of many of our great towns, would appear to be unworthy of the attention of anyone who had really mastered the principles of garden design. Any garden owner should, apparently, be able to lay-out effectively so confined an area. Practical experience, however, tends to show that the larger the garden, the easier the lay-out. And, conversely, the smaller the area to treat the more difficult it is to obtain even a tolerable result.

I cannot, of course, give a design or designs applicable to every garden—and, in the interests of diversity, I would refrain, even if it were possible. It is rather *ideas* than *designs* which should prove helpful, but these can only be worked out successfully in practice if a few of the principles of garden making which apply to quite small gardens are mastered.

If an architect (house architect, I mean), really knows his business, in designing and arranging the exact site for a house standing in its own grounds. he will allow ample opportunities for the landscape gardener to arrange a pleasant outlook and, very probably, pleasing vistas from each of the principal rooms, as well as from a possible loggia or verandah and from the house terrace, if there be one. And this arrangement of gardens around the house is the very first thing the practised garden architect looks for. Now, with the small type of suburban garden we are at present considering, there is, almost certainly, only one outlook on to the garden, and that a lop-sided one, and often flanked by unbeautiful domestic and out-offices. It is none the less necessary to make the best of it.

For the purpose of the present article we will consider the lay-out of a rather typical garden strip, with an aspect not exactly calculated to make easy a wealth of colour near the dining-room window. A long bed, centred on this window, might, however, have a few bushes of mahonia, Berberis Aquifolium, to provide furniture at all seasons and, for the rest, might contain ferns, shade-loving bulbs and tubers — Scilla nutans and S. campanulata, erythroniums, trilliums, Anemone nemorosa and varieties of hardy cyclamens and perhaps muscaris—while certain herbaceous plants, such as many spiræas, the galegas, dodecatheons, primroses, polyanthus and other primulas, Campanula alliariæfolia, and even a good strain of our common foxglove will help to bring colour in their season. Among bedding-out plants the most satisfactory for such a position is, perhaps, the most effective of all—the tuberous begonia.

Fig. 1 should serve to show even the least experienced in garden-plan reading, how a satisfactory vista right

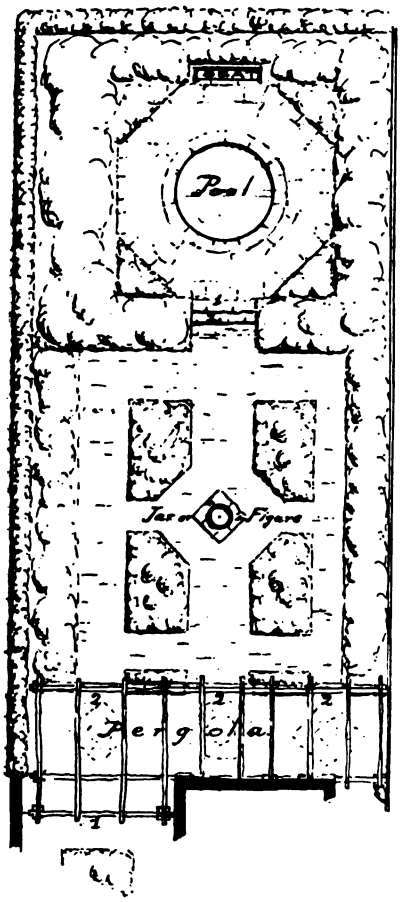


through to the bottom of the garden may be obtained without sacrificing the proportions of the component parts. The rose lover will certainly fill the four beds round the little sunken paved square with his beloved hybrid teas and pernetianas, while groups of roses will probably constitute part of the planting in the flanking borders. For those with different tastes plants with fragrant flowers and foliage would be suitable for these dwarf beds, and the greyness of foliage which suits so well with stone garden walls and paving happily often accompanies the fragrance. Thus we have the pink and carnation, hoary of foliage and fragrant of blossom, lavender and rosemary fragrant at all points, and many species of artemisia, delightful shrublets with silver or grey-green foliage laden with all the odours of pot-pourri. Several species and varieties of thyme and the wild marjoram of our chalky uplands may be added to a by no means exhaustive list.

The usual treatment in a suburban garden for the outside borders is a purely herbaceous planting, but such gives a very uninteresting effect in winter, and there is a multitude of small growing shrubs and such-like which are ideal for the small garden. Not that it would be well altogether to exclude herbaceous kinds from the small garden, or from such borders as these—let me not be misunderstood — but that in the really small garden, as in the very large one, herbaceous plants are better in combination with suitable shrubs than alone. With the aid of berried shrubs and coloured foliage, the laurustinus, winter-flowering heaths, Christmas roses, early-flowering bulbs and a solid background of flowering evergreens—we want no conifers here—such borders may be made quite cheerful in wintertime. (In the Midlands and North, where snow falls and hoar frosts are common, it is worth while to consider the decorative possibilities of trees and plants under wintry conditions.) And with bulbs, flowering shrubs, herbaceous perennials and numerous other subjects, the provision of flowers at other seasons is of the easiest.

The planting of the eastern and western borders need not be the same, but they must "balance" one another and there should be a general similarity about the planting which will unify the whole scheme. A hedge-backed seat ends the little formal garden in the design shown, and behind this a planting of shrubs or even small trees helps to form a setting for the turfed rock or wild garden, which may well be furnished

Digitized by Google



with stepping stones, for we should not neglect means of dry access when the raindrops still linger like jewels on many a lowly mountaineer transplanted to our rectangular suburban garden. The turfy ways—one cannot call them paths—are intended to be hollowed out into little vales so that the planting rears itself up on either hand, but the turfing should nowhere take on the character of real banking, while in places it may well be all but flat in cross-section. Diversity is the very soul of a small garden, but it will not, of itself, suffice. The curves and contours of the ground, those of the planting on either hand and of the few boulders employed, if resort is made to stone (and it can be used with admirable effect), should all combine together to produce a harmonious whole. Experiment will help the novice with his shaping and his building, but a real love for and knowledge of plants is necessary to foresee what modifications each little shrub will make, as it grows, to the sum total of effect. Let us not dwell too long, in this place, on this particular style of gardening. We shall find opportunity to discuss it further in a later article. But before leaving this plan the reader will do well to try to visualise the garden scheme as it is thus feebly shadowed forth and to see the why and the wherefore of each vista, curve and bit of planting.

Fig. 2 shows an alternative arrangement for the plain portion of the same site. Whereas in Fig. 1 we resorted to climbing plants and to a fairly solid border to obscure the blank wall of an unbeautiful outbuilding abutting on the garden proper, we have in this design arranged a pergola to serve the same purpose and to give a certain architectural character to the garden. But our pergola must not head the garden vista from the house, nor must it give a lopsided effect to it.

This plan is much more formal in its treatment than the one first considered and in many ways better, but —and it is a big "but"—ownership or security of tenure is necessary to justify one in building substantial pergolas or laying down pool gardens, for instance.

I hasten to add that the "pool garden" need have no water and need not necessarily be sunken, though such sinking adds much to the interest and effect. An octagonal bed might replace the pool, preferably raised up 9ins. or a foot above floor level and retained by formal or almost formal walling; or a well-head, not necessarily antique; or a figure, or a sundial in a little sunken garden of its own. Note that the heavier, mainly shrubbery planting round this garden is rectangular. The octagonal effect is produced by half squares of low planting in each of the four corners. A low retaining wall running quite round the garden, is, of course, an integral part of the scheme, but, where expense has to be considered very closely, a turf verge tilted rather steeply would not form too bad a substitute. And an Irish yew or a rambler rose on a square pole does not form an altogether unworthy understudy for a bit of statuary or a sundial. In any case, beware of the cheap vase, sundial or bird bath turned out by the thousand and, in all probability, of no particular intrinsic beauty.

Rather get a stonemason to make an unpretentious one for you, or get a bricklayer who loves his craft to scheme one out. The first requisite of a garden is beauty, and beauty comes from unity and repose. But if we must live with a garden we need more than beauty, we must have a measure of originality. The writer cannot understand the mentality of those who slavishly copy work in another garden, whether that garden be situated in England or in Italy. The best of designing one's own garden is that it is one's own. It may have many shortcomings, but at any rate it will to some extent—falteringly at times and blunderingly at others—reflect one's own conceptions and personality. And a garden is more adaptable than a house, so that as time goes on and one's touch becomes surer, one may hope to bring conception and execution more nearly into line. R. V. G. W.

SWEET PEAS FOR AUTUMN SOWING

GOOD AND INEXPENSIVE VARIETIES.

(*Continued from page* 582.)

THERE are now so many excellent varieties in almost every colour class that it is largely a matter of personal taste which one chooses. Good varieties cost no more to grow and little, if any, more to purchase than inferior ones, and it is certainly folly to waste time and money on the latter, when the very best are, comparatively speaking, so inexpensive. I do not claim that the following kinds are the very newest in their respective colour sections, but all are well tried and excellent for home or garden decoration. The great majority are also first-class exhibition peas as well. I give them in alphabetical order and have made no attempt to indicate which is the best in each colour section, for this, too, in most instances, is a matter of personal taste, requirement, and one's district.

WHITE.—Constance Hinton, Edna May Improved, Florence Wright Spencer Improved.

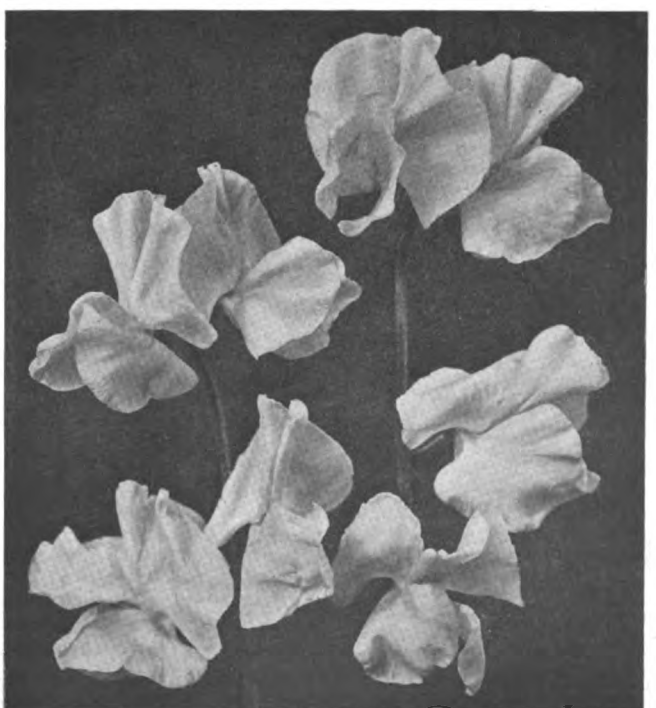
CREAM.—Daffodil, Majestic Cream, Matchless.

CRIMSON.—*Charity, *Crimson King, *Unwin's Crimson.

CERISE.—Charming, Coralline, Doris.

CREAM PINK.—Cecily (light), Fair Lady (light), Mrs. Arnold Hitchcock (light), Picture (deep).

SALMON CREAM-PINK.—Miss California, W. J. Unwin.



THE SALMON-PINK BLOOMS OF W. J. UNWIN.

Digitized by Google

PICOTEE.—*Annie Ireland (white ground), *Improved Jean Ireland (cream ground) *Youth (white ground).
PURPLE.—Royal Purple, Purple Perfection.
MAROON.—Splendour (chocolate), *The Sultan (black), *Warrior,
MAUVE.—King Mauve, Mauve Beauty.
BLUE.—Blue Butterfly (light), Commander Godsal (deep), Mrs. Tom Jones (medium).
LAVENDER.—Austin Frederick Improved (rosy), Gladys (lilac), Powerscourt (lilac), R. F. Felton (rosy), Wembley (light).
ORANGE-SALMON.—†George Shawyer.
SCARLET-CERISE.—Grenadier, Pimpernel, Royal Scot.
SCARLET.—Camp Fire.
ORANGE.—†Guinea Gold, †Royal Sovereign, †Wizard.
ORANGE-SCARLET.—†Mammoth, †May Cowdy, †May Unwin.
BLUSH.—*Elegance (silvery lilac), Felicity (pink), Valentine (pink).
PINK.—Hawlmark Pink Improved (salmon), *Hebe (rosy), Mrs. Charles W. J. Unwin (salmon), *Supreme (china), Tom Sykes (scarlet-pink).
ROSE.—Rose Maiden, *Sunset, Wild Rose,
CARMINE.—*Mascotts' Ingman, *Renown.
FLUSHED.—Advance (white ground), Comrade (cream ground), Improved Conquest (white ground), Improved Faerie Queen (cream ground), Mrs. H. Richards (white ground).
BICOLOR.—*Bonfire, *Dora, *Mrs. Cuthbertson.
SALMON.—†Barbara, †Melba.
STRIPED.—*Lady Gay.

Of the above, those varieties marked with a dagger (†) need shading in bright sunshine to retain their full colour, and those indicated by an asterisk (*) usually give a more even and quick germination if their seed-coats are slightly "chipped" before sowing. C. H. A. S.

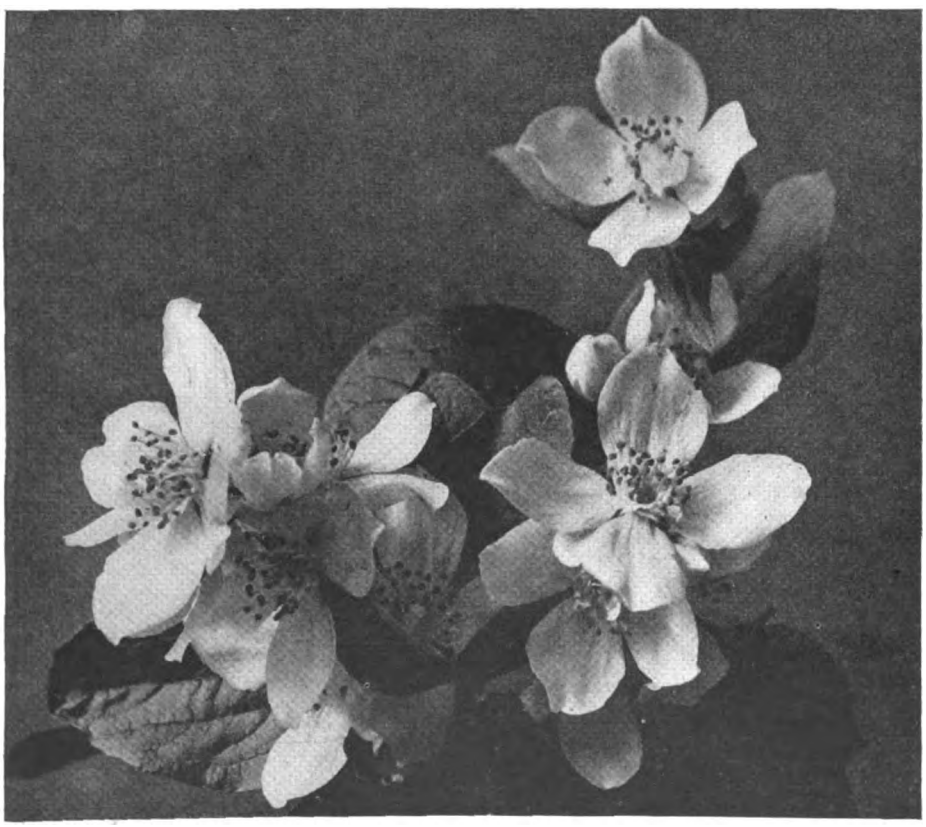
A SELECTION OF FRAGRANT SHRUBS

FRAGRANCE in the shrub world may be met in every direction, and lavish indeed is the range of subjects that await the planter's selection. There is, in fact, practically no limit to this, and whether it is proposed to plant out a large shrubbery, a few specimens in the general garden, clothe some of the larger boulders in the rock garden, screen the house walls or furnish the pergola with blossoms and fragrance, the only difficulty likely to be encountered is that of deciding which to reject. A complete list would fill a volume, but I give below a few important fragrant shrubs.

Absolutely hardy everywhere and a popular favourite with all, the fragrant jasmine may be used for clothing the supports of the verandah, climbing the house walls (with a very little assistance), or forming a bower-like mass upon the supports of the pergola. This is always fragrant, whether one visits it at noonday or midnight and, also, it is ever crowded by hosts of visiting insects that add not a little to its charm.

For fragrant leaves, we must have the sweet bay—Laurus nobilis—that is so decorative when used as a hedge or grown in standard form. Breaking upon us in a blaze of fiery brilliance in late May or early June, the hardy azaleas provide a colour picture to which it is impossible to do justice in mere words, while the sweet fragrance also leaves one equally tongue-tied. These are a striking lesson in the value of massing and we should never, unless absolutely forced by restriction of area, use them as single plants: a remark that applies with equal force to the question of fragrance as well as colour display.

Sarcococca ruscifolia is not a familiar name, but it is a most valuable evergreen shrub, whose special merit is that it will thrive under trees. A small and compact grower, the shining green leaves are ornamental throughout the year, while the small fragrant white flowers add not a little to its attraction. Among the honeysuckles we have a wide choice of delightfully perfumed flowers which may be chosen in order to provide a succession through many months of the year. It may come as a surprise to some to hear of a winter-flowering species of these, but it is by no means a plant to omit from the fragrant garden. Its name is Lonicera fragrantissima and it bears small drooping white bells all through winter and early spring, whenever the weather is sufficiently mild. A good companion to this is L. Standishii, in which again we have creamy white flowers from November to March.



THE HANDSOME BLOOMS OF PHILADELPHUS CORONARIUS.

The syringa or mock orange of the gardener is the philadelphus of the nurseryman and, where a hardy floriferous, vigorous and fragrant plant is desired, it would be difficult indeed to beat the old Philadelphus coronarius. Hybrids and species may produce larger or better blooms, but the old-time forms yield to none in penetrating odour, a fact of which full use should be made in those parts of the garden that are much frequented in early summer. The true syringa is known to gardeners as the lilac, and is such a universal plant that we need say but little about it. Its perfume is beyond praise, but it is a bad flower for standing wet weather and, for this reason, should not be too extensively used in small gardens, especially as the growth is rather rampant, and thus one is left with a large mass of green through the remainder of the season. Another powerfully odorous early summer shrub or small tree is the single May, whose flowering is synonomous with the month after which it is named, and gorgeous broad effects of colour are readily produced with this, where space permits of large subjects being boldly used. Fothergilla alnifolia is a low-growing plant that deserves to be much better known, for it provides us with splendid effects in both spring and autumn. Of low-growing habit, the flowers are borne on naked branches in April and May and one cannot approach it without being aware of its fragrance.

Digitized by Google

Following the flowers come the berries and, with the advent of autumn, these give us a magnificent colour picture that is very charming. The common elder is powerfully fragrant where a plant of large size is required, and a bold bush of this always looks handsome both in flower and when covered by the flat heads of purple-black berries.

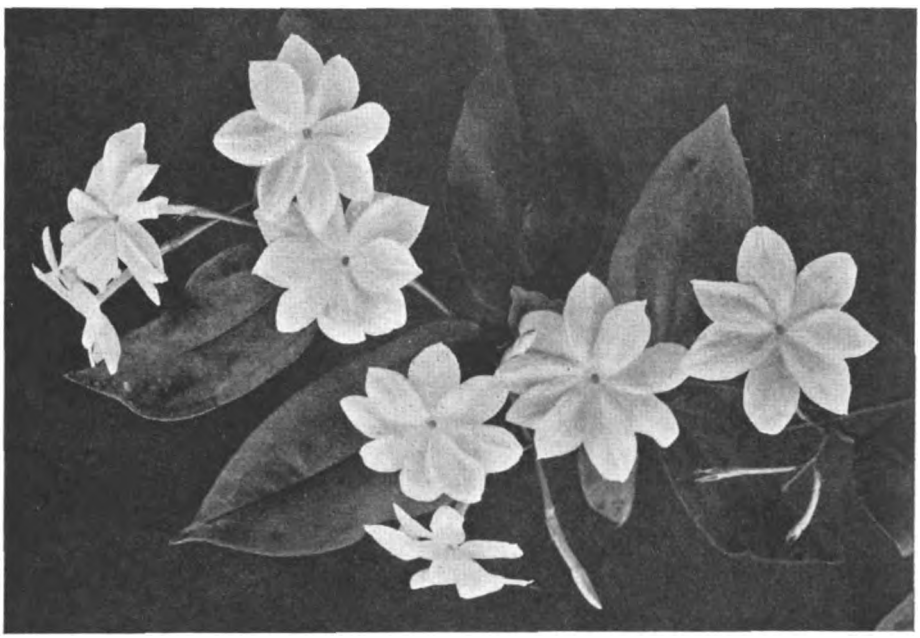
One is so used to the privet as a hedging plant that is kept severely trimmed, that it is very easy to forget that it flowers. But it does, and the white spikes of bloom in July and August have a distinct perfume that is especially in evidence at night. For clothing an ordinary garden wall, Azara microphylla is a very beautiful and perfectly hardy shrub with small, glossy deep green leaves. The flowers are inconspicuous but, from our point of view, extremely valuable, for they smell delightfully with a perfume that strongly resembles vanilla.

Every part, including the root, of the Carolina allspice, Calycanthus floridus, is fragrant and when bruised it gives forth a camphor-like odour that is distinctly refreshing. The flowers, too, are worth notice and are purple with a reddish tinge, produced in early June. A new and somewhat expensive berberis is japonica hyemalis, which flowers from October until early spring. The blooms are borne in racemes that are held almost horizontally and are pale yellow in colour and very sweetly scented. The white Portugal broom should not be overlooked where a free-flowering and striking light-coloured plant is wanted. This is unrivalled for planting in a dry position and one may rely upon a generous supply of flowers being produced annually when once the plants have become well established.

Dwellers in the West of England or other favoured spots may revel in the possession of that beautiful shrub, Drimys Winteri, a gem that is beautiful in either leaf or flower. One can envy, but not hope to emulate the wonderful specimens of this that are to be found in some Cornish gardens. From our present point of view, it is the leaves that contain the fragrance and these are deliciously aromatic when crushed, although we must spare a word of praise also for the delightful ivory white flowers that, when expanded, contribute their share of perfume. The Virginian fringe tree, Chionanthus virginica, is a very handsome May-flowering shrub that is especially happy when planted in a cool, half-shady site. The flowers are in the form of long clusters of white fringe-like petals and smell delightfully.

Though we come to the daphnes at the end of our notes, this does not mean that that is their place as regards value. Far from it, for they provide several indispensable plants for the shrubbery border and the rock garden without which we should be considerably poorer. D. Blagayana does not exceed 6ins. and bears its clusters of creamy-white flowers in early spring. D. Cneorum is slightly taller with round heads of pink flowers, so freely produced as practically to hide the leaves. The Mezereon, D. Mezereum, will flower from January onwards and reaches a height of 3ft. with branches closely packed with purple flowers that are extremely fragrant, especially when brought indoors.

H. W. CANNING-WRIGHT.



THE JASMINE, ONE OF THE MOST FRAGRANT OF GARDEN SHRUBS.

NOTES OF THE WEEK

SPIKENARD.

THE true spikenard, Nardostachys Jatamansi, is a pleasant, neat little plant with umbels of pinkish white flowers like those of the valerians, to which it is closely related; but these modest good qualities are not sufficient to merit a place for it in many gardens, and it is not likely to be grown except by those who are interested in its history or in its peculiar and once famous scent.

It makes pale green tufts of narrow, spear-shaped leaves, slightly serrated at the edges, which are scentless while they are alive but develop as they wither the characteristic mangy-dog smell of the valerians. The virtue of the plant is in the shaggy roots, which, even when fresh, smell strongly of patchouli with a slight added sweetness, perhaps of musk. The scent gains in strength as the root dries, but it tends to take on a faint valerian quality which seems to come from the thicker fibres.

The roots are still collected in Bhutan and Nepal, but they are no longer worth more than their weight in gold, for the introduction of patchouli has ousted them from the Western markets. Although the two plants are so different botanically—for patchouli (Pogostemon Patchouli) is a labiate—their scent is almost identical, and it is curious that a perfume which cannot be described as sweet, but has been compared with cedar-wood, moss, dried bracken, sable fur, old clothes and other things, should make so powerful and widespread an appeal.

Spikenard has lent its name to several other plants. Valeriana celtica, the "speick" of the Austrian Tyrol, was at one time exported in large amounts overland to the East as European spikenard, for although it smells powerfully of valerian, it has some of the patchouli quality as well, and is, perhaps, the least disagreeable of its family. Valeriana Phu, whose odd specific name seems to be just the Greek equivalent of "phew!" is known as Cretan spikenard, though the writer has not been able to find anything more pleasant than a valerian smell in the variety most commonly grown in gardens, the butter-coloured V. Phu aurea. This smell is apparently pleasing to some people, for V. officinalis is said to have been used in the Middle Ages for scenting clothes, and its dialect name "Setwall" is apparently a corruption of the word "zedoary," applied in the general sense of an aromatic root. One of our native composites, Inula Conyza, is sometimes known as ploughman's spikenard, and as spikenard the writer recently received a plant of Mentha Requieni.

Nardostachys Jatamansi comes from high, damp places in the Himalayas and is quite hardy in this country, where it seems to prefer a spongy, peaty soil that is not allowed to get too dry in summer. Here it seems quite happy in the company of some dwarf rhododendrons and Rubus arcticus.—F. A. H., *Chesham Bois.*

WINTER FLOWERS.

APART from Christmas roses and winter jasmine, there are quite a number of plants that flower during the winter months out of doors. Long spells of severe frost are unusual and, generally speaking, the typical English winter is somewhat mild, even if damp and windy. Here are a few plants which, during an ordinary season, will really flower in the open during the dullest months of the year. The handsome Kaffir lily (Schizostylis coccinea) is perfectly hardy and develops its spikes of crimson flowers in November and December. It is best to plant this species by the side of a wall or fence and, if the border has a south aspect, so much the better. The flower spikes being tall should be tied to stakes or they may be broken in rough weather. Even to-day many gardeners do not realise the beauty of the winter-flowering irises. One of the easiest to grow is I. reticulata,

Digitized by Google

which develops its violet and gold flowers in January. Other species well worth notice are I. stylosa, I. persica, I. Histrio and the scorpion iris (I. alata). The latter is especially worthy of attention in that it will develop one crop of flowers about October and then, in December, another display of blooms is given, which is generally at its best about Christmas. All the winter-flowering iris should be given a sunny, dry border, where they will be somewhat sheltered from rough winds, which would tend to damage the delicate blossoms. The strong growing saxifrage (S. cordifolia), is generally described as flowering about March. In a sheltered part of the garden the plant produces its rose-coloured blooms quite early in February, and it may therefore be included among the winter-flowering species. The winter heliotrope (Tussilago fragrans), produces its purplish flowers, which are delightfully sweet-scented, in January and February. This plant is just as easy to grow as the common coltsfoot. At least two of the hardy heaths flower in winter. These are Erica carnea and E. lusitanica. One or two of the hardy Zephyr flowers (Zephyranthus) produce their crocus-like blossoms as early as January. Thus Z. gracilifolia makes itself perfectly at home in a warm, sunny border and produces its beautiful rose-coloured flowers in great abundance.—S. LEONARD BASTIN, *Bournemouth.*

MONTBRETIA ROSEA.

MONTBRETIAS are classed under the heading of hardy herbaceous perennials and rightly so, as they rank among the most showy and useful border flowers, blooming profusely for several weeks throughout August and September. The flowers, too, resist wet weather better than those of many other plants, and are also much used as decorative material for dinner tables and room vases.

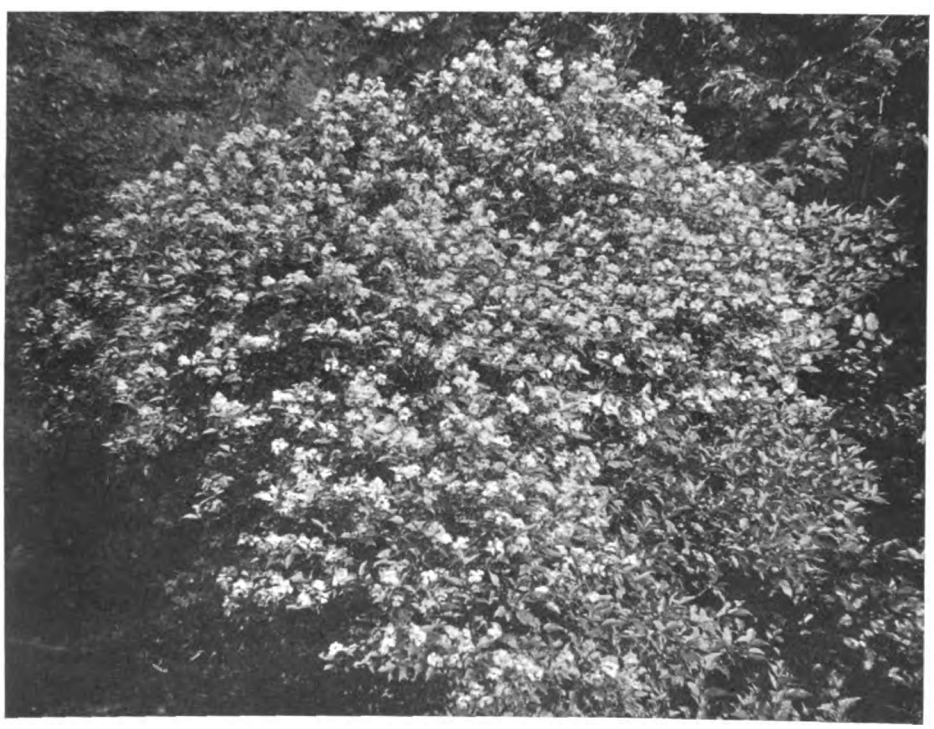
The beautiful pink variety known as M. rosea is rather a choice coloured kind and certainly quite apart from the host of reddish orange and yellow shades which dominate this graceful family. A good open position should be chosen for rosea and if the soil is heavy a sandy compost should be added to each station before planting the corms, as the rose-coloured montbretia is not such a vigorous grower as some of the other kinds, such as the old crocosmæflora or George Davison.—DAVID ARMSTRONG.

CORNUS RACEMOSA, A HANDSOME FREE-FLOWERING SHRUB.

THE cornel shown in the illustration is better known in some gardens as Cornus candidissima or C. paniculata. The oldest name, C. racemosa, is certainly a very inadequate one, because the inflorescences are not racemose, but form rather broad panicles. The name, candidissima, is very designative for such a plant laden with its snowy white blossoms.

This species was introduced many years ago, and is a native of the Eastern United States from Maine to North Carolina, and westward to Minnesota and Nebraska. I took the picture in the Arnold Arboretum years ago about the end of June. With us it sometimes flowers even later, and, as Mr. Bean states, it has much to recommend it as a late-flowering shrub. But he adds, "unfortunately it does not set its fruit here with the freedom that makes it so attractive in the United States," and I can add, on the European Continent, where I have seen good plants with their white fruits on bright red peduncles in the autumn.

C. racemosa is of a rather close, bushy habit, forming fine plants up to almost 16ft. in height. In the Arnold Arboretum a fine hybrid, C. Arnoldiana, between this species and C. obliqua (C. Purpusii), originated about thirty years ago. It flowers rather freely and even somewhat later than C. racemosa, but the fruits are very scarce. They are bluish. The habit of C. Arnoldiana is more like that of C. obliqua, a broader, more loosely branched shrub. While C. racemosa has greyish branchlets, the wood of C. Arnoldiana is purplish. C. obliqua is closely allied to C. Amomum or C. sericea, a well known species that has already been introduced from eastern North America in 1683. Its main feature is the silky brownish pubescence underneath the leaf.—CAMILLO SCHNEIDER.



THE BUSHY AND FREE-FLOWERING CORNUS RACEMOSA.

SOLANUM CAPSICASTRUM.

THAT bright orange-red and green-berried shrub, Solanum capsicastrum, is much in request about Christmastime for table and window adornment, and while one may cut back old plants after their fruiting season, re-pot, and grow them on, it is really from young plants that one may look for the best results. When it is remembered that one may sow seed in the warmth of a greenhouse in March, prick off the plants when well into their second leaf, and subsequently pot them twice, the final shift being into 4in. pots, it scarcely seems worth while troubling with old plants that not infrequently drop their flowers, if unattended to with water, at the first sign of dry weather. Summer treatment is met by plunging the pots up to their rims in fine ashes in a cold frame, with the lights off for the most part. It is an advantage to have the frame in a north position, to secure shade for a portion of the day. That is a practice which is generally followed, but of late years I have met with instances where Solanums, instead of being potted finally, when ready, have been planted out and left until September. What particular advantage there is in this I do not know, unless it minimises the trouble of watering somewhat; but it seems to me that to cram into a pot roots which by early autumn have spread, and at a time when the plants are full of green berries, is very risky and is likely to stop progress. Potting has to be done, no matter whether it be in June or September, but the earlier month is surely the better of the two. One cannot treat solanums in fruit quite like some other plants.—W. LINDERS LEA.

ABELIA SCHUMANNII.

THIS, a recent introduction from China, I consider to be the most beautiful Abelia yet introduced. It has especial merits which cannot fail to make it become a favourite with all who see it. With us, it makes a somewhat spreading bush, the young branches being pendulous with the weight of flowers, which the plant produces in the greatest profusion.

In colour it is distinct from other varieties of abelia, the flowers are produced from every joint of the young growth quite to the tips, and occur from pairs to as many as six to each joint. These are closely followed by a second crop on short lateral growths, easily making it the most free-flowering of all abelias. Their colour is a beautiful pale mauve with white throat and small orange blotch. They are 1in. in length by ⅛in. across the mouth. Generally, in shape they resemble a small pentstemon flower. Individual flowers remain on the plant for several days. Another point in its favour is its prolonged flowering period, the first flowers this year being produced in early June—they are still in full flower, and will continue so for several weeks to come. Also, it is evergreen, its foliage being about 1½ins. by ½in. in width and closely set in pairs upon the branches.

Owing to its fast growth and long, pendulous shoots, it is admirably suitable for a wall plant in the colder parts of this country. It thrives in good loamy soil, and does not mind lime.—JOHN HILL, *Paignton.*

PLANTS IN THE DWELLING-HOUSE.

THERE are many thousands of pot plants kept in dwelling-rooms in both good and poor conditions. The ventilation, the light and the general treatment has much to do with the condition of the plants when the latter are suitable kinds for the purpose. Where a greenhouse is available, it is very useful as the plants can be changed oftener than in cases where there is no greenhouse. Even a good, deep frame is a great help. I am not referring now so much to window plants as

Digitized by Google

to those used as specimens in vases on tables in the rooms and halls. Naturally, such plants will not retain their normal health as long as those growing in large windows. Gas is bad for plants; electric light is much better. Open fires are better than stoves. It is not wise to attempt to grow very tender kinds of plants; those of a hardier nature will give the greatest satisfaction. Great things may be done with bulbs in season, and many thousands of these will be used in the dwelling house. They can be grown throughout without the aid of a greenhouse or frame—hyacinths, tulips, narcissi, snowdrops, scillas and crocuses. The berried Solanum capsicastrum is very fine in the autumn. For affording a patch of vivid colour the salvia is splendid, but the plants must be very carefully watered and never subjected to draughts. All plants will need careful watering as the rooms are warmed now. Clear water only should be applied, and no stimulants given except to growing bulbs.

POPULUS EUPHRATICA, THE WEEPING WILLOW OF THE BIBLE.

WHEN I first visited the famous arboretum of the late Mr. Allard at La Maulévrie, near Angers, France, I was very greatly impressed by the peculiar aspect of two young poplars, of which I took the accompanying photograph. It shows the strangest of all poplars, the famous Populus euphratica or diversifolia. This Oriental species, which is so entirely different from all other poplars, really represents the "willow" of the Children of Israel. It is widely spread from Algeria, through Egypt, Syria and Mesopotamia to southern Persia, north-western India, Mongolia and even north-western China. Sometimes it becomes a tree almost 65ft. high with rather slender spreading branches and almost pendent branchlets.

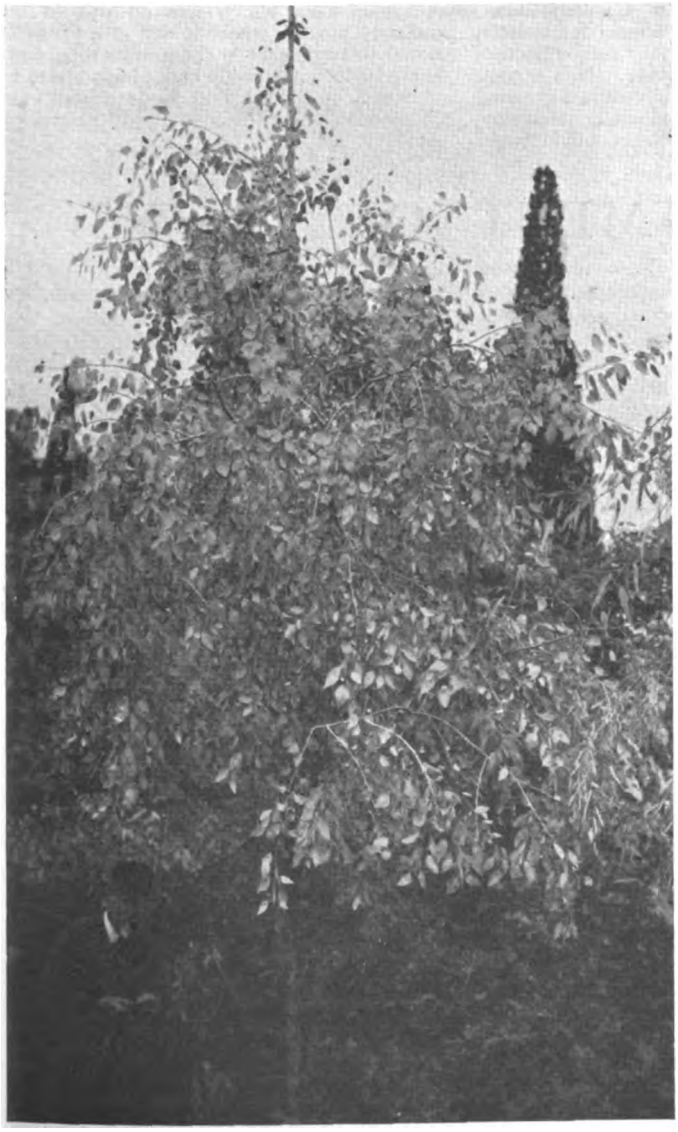
The shape of the leaves is very variable. On young shoots they are more or less willow like and entire, while on short shoots or older branches they become shorter and broader, rhombic or almost roundish, and more or less lobate-dentate. Both kinds of leaves may be seen on the same tree, but, as the picture shows, young plants often develop only leaves of one kind.

This strange poplar is not mentioned by Bean, and seems to be a rare plant even in British gardens. It likes, of course, a sub-tropical climate, but the forms of north-western China ought to be hardier.

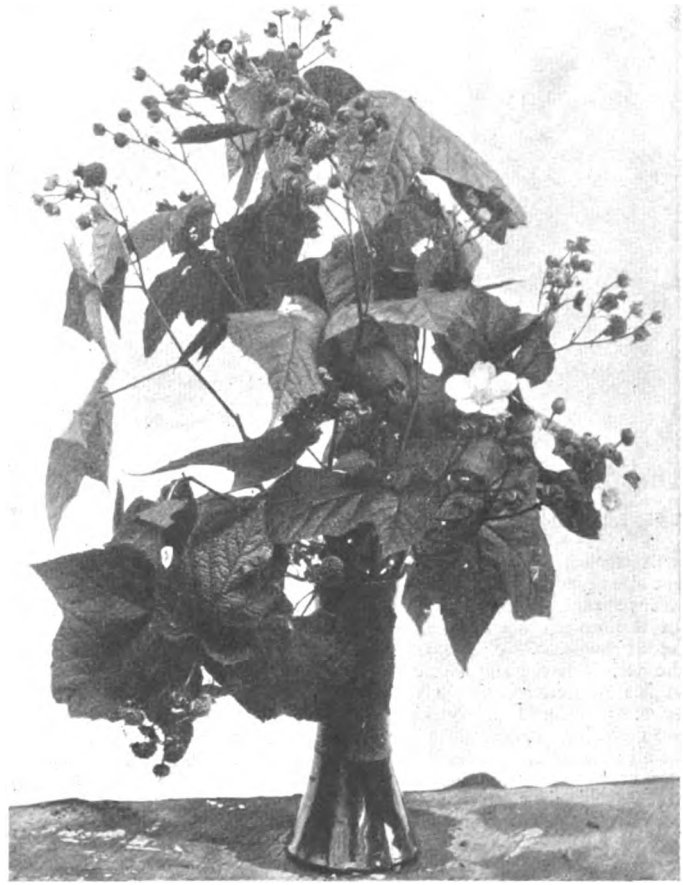
P. euphratica, to which P. ariana and P. Litwinowiana of Dode also belong, is the type of the section Turanga, with greyish green foliage, of which both surfaces are alike, and the downy buds are hardly viscid. The disc of the male and female flowers is rather deeply lobate at the margin, and the number of stamens varies from twenty to thirty. The ovary usually bears three stigmas. The glabrous bracts of the flowers fall off very early.

In a locality where it may be successfully grown this poplar is of the greatest interest to all lovers of peculiar woody plants.

CAMILLO SCHNEIDER.



A HANDSOME POPULUS, P. EUPHRATICA.



RUBUS ODORATUS, A FINE ORNAMENTAL SHRUB.

RUBUS ODORATUS.

DURING the months of August and September this ornamental rubus has been flowering freely, and this year quite a number of its fruits have been ripened. In the illustration both fruits and flowers can be seen, but the former are by no means numerous, and in proportion to the number of flowers on the plants the crop is a small one. Here, at Castleford, Chepstow, where the photograph was taken by my friend, Mr. M. Moulton, the plants are growing in a shaded part of a shrubbery and beneath a belt of pines. The stems attain a height of from 4ft. to 6ft., covered with vine-like leaves, and the flowers are borne in clusters at the end of the growths. Each bloom is about 1½ins. across, fragrant, and bright purple-rose in colour. The fruits are somewhat flat, red, and readily part from the core when ripe. The flavour is rather insipid. It is an admirable subject for semi-shaded positions; it is free-growing, and the stems are cut down to the ground level each winter. A native of eastern North America, and introduced to this country in 1770.—T. W. BRISCOE.

THE PARSLEY FERN.

MANY people have tried to grow the pretty parsley fern (Allosorus crispus), which, in certain localities, is so abundant in the north of England and Wales. As a rule these attempts have not been a success, for, even in places where the fern has not died right out, it does little more than hang on in misery. As a matter of fact, the parsley fern is quite easy to grow well even in a town garden if grown under the right conditions. Choose a bed with a northern aspect and insert the fern roots in a mixture of peat and loam. Naturally, the parsley fern grows up among rocks, and the best results are secured by half-burying the plant

Digitized by Google

A FINE DRIFT OF RANUNCULUS GLACIALIS

with fragments of stones. These should not be placed right on the fronds, but, strange to say, a good heavy stone almost on the crown seems really to encourage a free growth. A clump of this fern which the writer had languishing for several years in his garden was fully restored to vigour by the placing of a slab of rock almost on the top of it. The bright green fronds pushed out on all sides of the stone, showing that the fern was at last growing under happy conditions. Once established in this way the parsley fern goes on increasing from year to year, and one can then realise what a very beautiful species it is.—S. LEONARD BASTIN, *Bournemouth*.

RANUNCULUS GLACIALIS AND CROCUS PULCHELLUS.

I AM enclosing two photographs that might, perhaps, be of interest to readers of THE GARDEN. The photograph of Ranunculus glacialis I took on Piz Langard, near Pontresina, early in July. It was growing there in the loose scree with the greatest luxuriance, often carrying five blooms on a stem and the blooms being nearly 2ins. in diameter. Geum reptans, Androsace glacialis and Eritrichium nanum were all growing in profusion in the same place. I saw the ranunculus on several other high points round Pontresina, but nowhere else looking so well.

The second illustration is of a bloom of Crocus pulchellus which flowered in my garden. This bloom carried ten petals, while from the same corm two blooms had five petals only, the remainder being normal. Can any reader say whether this crocus is given to variation in this way? I have had other blooms with seven petals.

My present stock of this crocus consists of seedlings from corms collected by me during the war on the hills above Kopriva in the Struma valley, Macedonia.—D. BLANCHARD.

PYRETHRUM CORYMBOSUM.

A GOOD border plant which appears to be strangely omitted from most hardy plant catalogues of the day is Pyrethrum corymbosum, which I saw after a long interval in the charming garden of Mr. C. W. Ralston, at Dabton, Dumfriesshire, where Mrs. Ralston and the staff cultivate a very fine collection of hardy flowers so admirably. It is a good hardy plant and useful for cutting, growing about 3ft. high, and producing handsome, dark green, finely divided foliage, and crowned

AN ABNORMAL BLOOM OF C. PULCHELLUS

with large corymbs of white flowers with a yellow centre. It is rather surprising to see it neglected in nurseries, especially seeing that it is marked with an asterisk, denoting it as a plant of special value in that standard, though now incomplete work, Nicholson's "Dictionary of Gardening." When that great work is brought up to date, this pyrethrum should, I consider, still retain the mark of commendation. It is a truly hardy plant, and one, also, which will do well in any ordinary border, where it will give plenty of flower in summer. At the present time, however, I do not know where plants are to be obtained, nor do I find seeds offered even by specialists in those of hardy plants.—S. ARNOTT.

THE AUTUMN TREATMENT OF LAWNS

MUCH activity is noticeable on lawns, tennis courts and bowling greens, and great is the need, for the long-suffering grass that has endured six months' hard wear, close cutting and, generally, a great deal too much rolling cannot recuperate unless assisted by judicious treatment while there is yet warmth in both atmosphere and soil. Unfortunately, a large proportion of the activity one observes may more accurately be described as misdirected energy than as judicious treatment. A lawn that has been trodden and rolled until the surface of the turf is as tightly compressed as a rubber mat will not benefit by being covered with a thick layer of wet, binding pit sand such as builders use for making mortar, but one may see lawns thus treated, the sand being rolled until it forms an almost waterproof and airproof sheet over the whole herbage. Little better is the fate of the lawn that is afforded nourishment in the form of an inch thick coat of short stable manure, once more forced tightly down upon the crowns of the grass by the heavy roller. Lawns require nourishment; they may also require sand; but each must be used with due regard to fitness.

Whatever else may be required, the first thing every lawn should receive at the end of a season's wear and tear is a thoroughly good sweeping. Should the surface be closely compressed, it is well to follow the sweeping by scratching with a sharp-toothed steel rake; and if badly hidebound—a term used to denote the condition brought about by heavy treading or over-rolling—perforations of the turf will do an immense amount of good.

One of Pattisson's spiked rollers or the spiked attachment to the "Atco" motor mower is of vastly greater benefit to a hard-worked tennis court than the hose and sprinkler; but for small lawns an ordinary garden fork may be thrust perpendicularly into the turf to a depth of 3ins., persevering with the work until the whole lawn is studded with small holes about 3ins. apart. These holes should be left open for a week, the object being to allow air to percolate into the soil about the roots of the grass.

In the meantime a good top-dressing should be prepared, and the precise character of that top-dressing should be governed by individual circumstances. A lawn resting on heavy clay or on a spongy soil that holds a great deal of moisture will benefit by the use of sand, but the sand must be clean, sharp, and have no tendency to binding. A good grade of sea sand is very useful, river sand or Bedfordshire silver sand being alternatives. If, on the other hand, a lawn is laid on dry, porous, sandy soil, either good, sweet leaf-mould or clean turf loam, finely sifted, will make the best dressing. Whatever soil is used should be free from weed seeds and from fungi or the eggs of ground pests.

Some kind of fertiliser must be incorporated with the top-dressing, but at this season of the year the need is not for a stimulant of rapid action, but rather for a stolid organic fertiliser that will improve the soil, dissolve or decompose slowly, and be available when the roots of the grass resume activity in spring.

Finely powdered hoof and horn meal is an excellent grass food. Bone meal is highly nutritious, but its tendency to encourage clover is a disadvantage on playing greens, where the slippery leaves constitute a danger to players. Various chemical firms make up special lawn manures for autumn and winter use, and there is much to be said in favour of using a lawn manure prepared by a well known firm.

Make it an unalterable rule never to give a heavy top-dressing at one time. A quarter of an inch thickness is ample for any one dressing. A fortnight after application brush the lawn vigorously to and fro with a good birch broom, and as soon as the top-dressing has disappeared apply another dressing. It is better to top-dress three times between October and March than to give one thick coat.

Lawn sand may be applied now to kill daisies, plantains and other broad, flat-leaved weeds. Crowns injured now by the caustic agents in the lawn sand will rot during winter, whereas in summer they often contrive to sprout from side crowns. Where lawns are infested with weeds of upright growth or narrow foliage it is prudent to hand-weed before top-dressing. A. J. MACSELF.

THE BREAKING OF TULIPS

IN plant life there are many aspects similar to, but not exactly like, the feature of the breaking of tulips, their variegation from the self-coloured to the broken forms of blooms. This characteristic trait of the tulip plant, its custom of breaking or rectifying, is in many respects probably unique.

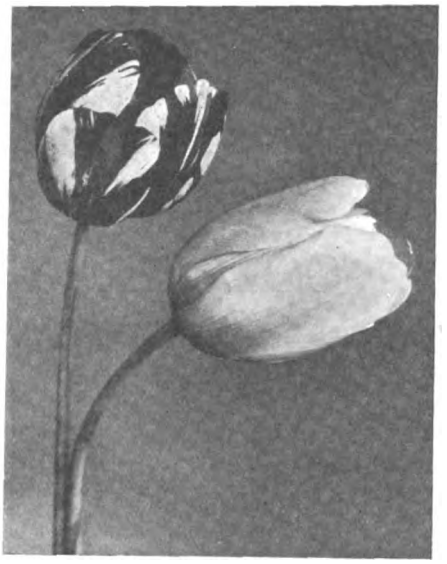
Centuries ago tulip lovers highly prized those blooms which had markings on their petals, that is to say the colouring matter was not suffused or evenly spread over the whole petal, but broken up and its particles of colour grouped together in regular or irregular forms, whether on the edge of the petal only or in some figuration of stripe or flame over the whole petal, and revealing more of the yellow or white ground colour than is seen in the self-coloured flower. The body colour may form shapes that are regular, identifiable and distinguished, such as feathered forms or flamed forms. In some varieties the break gives a mottled or marbled appearance to the colour of the petal, or perchance the petal is flaked with colour merely, and has lost the whole-coloured look. Some broken flowers look as though the colouring matter, if fluid, had gone sour, and lost its coherency; it may be the colouring matter is semi-fluid.

When the pigment—antho-cyanin—is thinly spread on the inner side of the skin of the petal, it seems to break more readily than is the case when the pigment is spread thickly, or is denser.

Darwins, with their thicker and fuller petals, do not seem to break so readily as the thinner-petalled varieties of the English group, or of some varieties of the Dutch and the garden groups; probably the stouter and sturdier varieties carry blooms with thicker petals than some of the more tender varieties can carry.

A short study of the life and habits of tulip plants will reveal characteristic tendencies that are very interesting, and some features that are fascinating, and the cultivator's mind is puzzled with considerations of the causes of the phenomena he observes; further observation and study only serve to make the mysteries deeper.

Blooming first from seed, a flower comes self-coloured, the resultant bulb may in a year or two, or in some years, throw a bloom that is figured or marked, the colouring matter of the petals having intensified and broken up into regular or irregular groups. In some cases the leaves of the plant also exhibit variegation, the chlorophyll having a somewhat streaky or striped appearance; there are, of course, broken varieties, the plant-leaves of which are indistinguishable from the leaves of plants of the same variety in the self or "breeder" stage. One does not change the name of the variety because it has broken—not in these days, at least. One's experience is that all tulips will break, sooner or later; we believe, however, there are tulips still persisting in the breeder stage that are a hundred years old, some we have seen, though most of the progeny have broken.



A TYPE AND ITS BREAK.

In the old days tulips that were broken were the desired blooms. Lovers of the flower who best knew its possibilities, had evolved certain kinds of broken forms: flowers that were feathered and flowers that were flamed—these were fine tulips.

Flowers that were in the preliminary self-coloured stage, breeders as they were termed, were tolerated and appraised for the inherent power they possessed of breaking, possibly as improvements on the parents from which they were raised.

The desiderata of those days were the form of the flower, the purity of its colour and the quality of its marking. In these aims great improvement was achieved by the old-time florists—to some extent, perhaps, in the case of the earlier English florists, at the expense of the constitution and vigour of the plant. In the case of the true Darwins, sturdiness is more in evidence, together with a lesser tendency to break. Whether delicacy of constitution increases the tendency to break or robustness of constitution mitigates the tendency is not yet established.

Let it be stated here, in parenthesis, some modern English florists have produced seedlings lacking nothing in vigour of constitution or purity or brilliance of colour. Such examples of recent origin are, as yet, alas, few in number.

The mystery of the break! Is it constitutional and inherent in the plant, and may it be promoted, perverted or stunted; or, not being an inherited trait, is it due to climate and environment, or to some disease that plants are liable to in general, and tulip plants in particular? When plants get old—that is, are a long time from seed—they seem to be more subject to disease, and to insect attack, which impairs the vigour of the plant even if no disease is thus communicated; often these older plants succumb to attacks that more youthful plants resist and ward off. We may see that some varieties exhibit a greater tendency to break than others, and some soils, or particular environment, seem to help the break; it may be found that a lessened vigour of constitution, resulting from starvation of treatment in plant life or ill-usage of the bulb in its quiescent stage—though plant life still goes on within the bulb—may induce break; can our learned plant pathologists tell us what causes the break in the first instance?

We see its results in both foliage and bloom, and note a diminution of vigour and a reluctance to yield off-sets, which phenomena may be relative to the break or may be due to poor nutrition, wrong environment or other causes. While

THE RECTIFIED FORM OF TULIP CORDELIA.

Digitized by Google

many new seedlings bred from broken forms readily break and do not persist for more than ten years—some die out earlier, others later — there are varieties existing in the broken form that have " carried on " for sixty, some seventy, some have endured for one hundred years.

There are healthy and vigorous varieties, nearly a century from seed, still growing, and under proper treatment giving offsets, that have not been seen in the breeder stage in the memory of living man. If there be a disease, do some varieties become " immune," but never revert to their former stage, never throw self-coloured blooms ; do they, so to say, retain their " pock-marks " and still thrive ?

Many growers say that tulips have " gone back " to breeder, some say that seedlings have first bloomed in the broken condition and then reverted to the self-coloured stage ; actual evidence is wanting. It seems to emerge from our experience that " once broken, always broken," is the rule of the tulip plant, and that tulip seedlings first bloom as breeders or selfs.

In 1860 Headley records that out of a group of tulips he desired to break, only one out of twenty actually did so, and that one had been seeded. He afterwards tried similar methods with the others of the group, but finally gave up growing them, regarding the task of inducing break to be hopeless.

It was noted that breaks occurred equally in each kind of soil, so that one could not say a particular soil—such as a limy soil—made the break. In 1913 a year when many tulips broke with me, one bed of 120 bulbs of Clara Butt all bloomed in a feathered state ; these were solid in colour the previous year, the stock coming originally from Walter Ware, had been with me four or five years ; analysis of the soil showed a deficiency of nutriment, especially lime. It seemed to be established that it was a peculiarity of the season that caused the break.

(To be continued.)

C. W. NEEDHAM.

COLOUR FORMS OF ALPINE PLANTS

THE cultivation of special colour forms is the hobby of at least one of our most successful coaxers of high alpines. This form of gardening is far from the beaten track, yet every catalogue and botanical work bears witness to the real appeal made by the unusual. Explain it as you will, everyone is intrigued by the discovery of a wild patch of white heather, or of a four-leaved clover, and if of white heather, why not of white Erica carnea, and so on indefinitely, until what seems the pursuit of an aimiable lunatic, such as the attempt to cultivate a white Eritrichium nanum, links itself logically to one of the commonest of human traits.

The colours of many alpines vary so greatly from poor to indifferent and good, that a general rule should be, to see your plant in flower before you purchase or collect it. To dig up a plant on the hills when not in flower is invariably to take the risk of rearing a poor colour form.

Generally it is the albino that is sought by the collector. Occasionally the albino is more beautiful than the type ; frequently it is no less beautiful ; very often it is inferior. The attraction, nevertheless, persists. As, however, the word " albino " is only less ugly than its plural " albinoes," I shall not use it again. The very luck of white heather might flee if it were called " the albino of Calluna vulgaris."

Colour variations of blue flowers are most frequent in the hills ; next come variations of pink or red flowers ; and, a long way behind, of yellow flowers. Do there exist blue, pink or yellow forms of white flowers ? Maybe — in New Zealand. Has any antipodean plant-hunter happened on a blue form of the normal white or pink gentian or forget-me-not ? (It is interesting to find that the Antipodes actually do something really upside-down.) From the mountains of Europe I suggest a few, though I doubt if even these will pass scientific muster. There is a deep rosy form of Ranunculus glacialis which may be culled in armfuls on a certain red granite scree and is not merely the normal white buttercup pink-tinged after fertilisation ; it is deep rosy-red from bud. There is a deep creamy variety also, which might be a hybrid were it not for the complete absence round about of any yellow buttercup for mate. Then in that alpine Garden of Eden, far Hoch Obir, beloved of Rainer, Saxifraga squarrosa is not white, but pale yellow ; and it is related that somewhere S. diapensoides erupts into citron. Again, Burser's white poppy becomes Kemer's yellow poppy ; but you may object that these are different species, though Burnat disagrees with you. There is also the cœrulesans variety of the white Anemone trifolia, but there are several blue- or pink-tinged forms of white anemones, and until I see a really blue trifolia I do not feel confident about it. As for Androsace glacialis, is its normal form the white that alone exists in the Dolomites or the pink that alone exists elsewhere ?

I imagine the above colour forms are all in cultivation here and there in England—except the white eritrichium. I doubt if anyone ever got that alive from its precipices above the Vial del Pan or Passo delle Selle. Myosotis rupicola is well known, at least in catalogues. Some deny that there is such a thing, distinct from alpestris, at least in Europe. They may be right, but in any case there is a very high alpine forget-me-not, dwarf, large-flowered, with conspicuous geometric white eye, which has a colour all its own. In naming it " dawn-blue," I am plagiarising because I must. It is the coldness of the blue of the dawn made concrete in a flower. Then, before I leave the borage race, there is an exquisite white form of Omphalodes verna ; and Sir Herbert Maxwell has kindly words for Pulmonaria saccharata in his garden, though in this it is not the flower but the white or dappled leaf that makes the variation.

The campanulas are in dire need of a critical monograph, but he who undertakes it must be dauntless. The more I see, the more confused I become. Whether in the English garden or in the blue expanses around Misurina, the alpine campanulas hybridise without propriety in themselves or compunction for botanists. I still think of Mr. Clarence Elliott delving among herbarium specimens at Kew (as he promised in THE GARDEN last year), in order to decipher for us Campanula linifolia. White and silver forms of linifolia, Scheuchzeri, and all the twelve tribes of rotundifolia abound, and all are hall-marked. The porcelain blues of barbata vie with its silvers. The octaves of colour of pusilla's bells make names such even as Miranda meaningless, and cæspitosa from the Karawankens has an equal compass. To say, as Farrer does, that rhomboidalis ranges from midnight blue through lilacs and china-blues to silvery tones and whites, is to describe most alpine bellflowers. There are brilliant white forms of cenisia, excisa, garganica. Trachelium, persicifolia and patula. The beautiful white C. glomerata, and a porcelain-blue one, which I have seen only once—in the Eastern Julian Alps—are markedly superior to the somewhat heavy purple of the type, and, growing in deep pasture, were distinguished by a grace which does not usually characterise the plant.

Of the most august of the campanulas I should leave others to tell. " In a note in THE GARDEN a little while back," wrote Mr. Elliott in December, 1923, " M. Correvon mentioned the white form of Allionii as growing in Dr. Jenkin's garden, but Dr. Jenkin tells me he has not the plant. As far as I know, live plants of Campanula Allionii alba have never reached this country." In THE GARDEN of January, 1924, M. Correvon accepted it, " that the plant has disappeared from English gardens, and I believe he (Mr. Elliott) is right." Early in July, 1923, when I met Dr. Jenkin on the Mont Cenis, he had collected a plant on the Nunda which he hazarded from the leaves—for it was yet too early for the flower—might be a white Allionii, and in the spring of this year the garden at Hindhead duly displayed in richest white the large Canterbury bell of Allionii in its best form. I am often at a loss to tell a plant from its leaves ; I expect now to be told it is a poor botanist who cannot tell therefrom the colour of the flower ! At this rate I look forward to seeing the crocus king devising some rare corm beneath the soil by means of a witch hazel ; or the Laird of Monreith introducing a breed of rabbit which will not devour his favourite shrubs.

E. ENEVER TODD.

CORRESPONDENCE

IRIS STYLOSA.

SIR,—I thought it might be interesting to the readers of THE GARDEN to know that Iris stylosa opened its first flower here on October 4th, and several buds are showing colour. The plants in question were only planted last spring at the foot of a stokehole wall, facing south-east. There is practically no soil where they are growing, only sandstone and cinder ash that the paths were made up with. Possibly the warmth from the stokehole accounts for it flowering so early.—A. J. SAMPSON, *Sussex*.

A NOVEL GARDEN DESIGN.

SIR,—Readers of THE GARDEN may be interested in the design of this part of my garden. Down the centre I formed a small "stream" some 6ins. deep and about a foot wide; this takes in the first place rain water, but is replenished by a hose pipe when necessary. This water course ends in a small, heart-shaped pool, in which I have a flowering aquatic. As a background finish to this pool is a small rockery, in which there are blue iris, Solomon's seal and montbretia. Although not seen from this point, a small weeping willow hangs over the water. In the broad herbaceous border are, as will be seen, violas, lupins (white, pink, blue and yellow), and forget-me-nots. Following these in due season are the usual perennials. The Michaelmas daisies in many varieties, are making a good show at the moment, with chrysanthemums, dahlias and cape gooseberry, and a fair display of late standard roses. Between the grass edge and the stream there is a small strip of soil planted with bulbs of all kinds to make a show for the spring, and the effects are most attractive.—N. M. WILSON.

A CORNER OF THE STREAM GARDEN.

COLOUR NOMENCLATURE.

SIR,—I was very glad to see the much needed article in THE GARDEN on the above subject. Some colourings in our flowers are indeed difficult to place, but there is no excuse at all for the loose and unscientific way in which the colours of some quite definite ones are misrepresented in nurserymen's catalogues. In 1917 I pointed out some glaring inaccuracies, such as Iris pallida dalmatica described as blue, together with our wild geranium and the violet, while the mauve Neapolitan violet is also described as lavender-blue. In one catalogue, picked up at random, we find Gladiolus Baron Hulot rightly described as rich purple, while in another it is said to be a deep indigo blue. The rich purple spring-flowering crocus is also described as blue; the mauve and white striped Sir Walter Scott figures as white with a blue stripe. The soft mauve Crocus Sieberi is catalogued as lilac-blue—it certainly cannot be both. Single poppy and St. Brigid's anemones are said to embrace shades of both blue and cobalt, but purple is not even mentioned! The same firm issue another catalogue in which the mauve wistaria is listed as a blue climber. Iris germanica is described as "the common blue flag," S, blue, F, purple. Most of us know that the standards of this flower are *not* blue, but a perfectly well defined rich purple.

In another catalogue a climbing rose is named Violet-Blue and is, or was, described as the nearest colour to a blue rambler yet raised. The true tint is a disagreeable faded puce. The word red is such an indefinite one that it might indicate any tint from a brick wall to a crimson or maroon-rose. The term salmon appears to cover quite as wide a ground, and therefore comes to mean nothing at all. I was glad to see "An Italian Reader" had drawn attention to the anarchy reigning in the description of yellow roses. Even the yellow crocus is wrongly described, if the fruit of the orange has a colour of that name. Again, there is a wide difference between the colours of the early purple orchis, the heather and the Iris germanica, yet they are all termed purple. Colour descriptions require a thorough revision throughout the whole range of vision and the old misleading descriptions scrapped once and for all.—H. H. WARNER, *Hoddesdon*.

TROPÆOLUMS.

SIR,—As one who grew Tropæolum tricolorum nearly fifty years ago, I should like to say what an interesting and showy plant the latter is when grown successfully. As your contributor, Mr. Hoog states, in the issue of THE GARDEN, September 26th, page 539, that if by any chance the thread-like growths are broken, the plant has to make a fresh start, and it is seldom that it recovers the same season. When growing freely, T. tricolorum requires almost daily training, otherwise the frail young green shoots are liable to become entangled. We used to train some plants to small trellises and others on birch shoots, similar to those used for making brooms.

Mr. Hoog did not mention T. azureum, which we used to grow in the same way. Its tiny flowers of lovely blue were much admired. It is even neater in growth than T. tricolorum, and although it is somewhat difficult to cultivate, the grower is well repaid when the plant is in bloom. These tropæolums were given similar treatment to that advocated by Mr. Hoog in his interesting notes. Tropæolums are evidently not often grown at the present day. It must be quite twenty years since I last saw them in cultivation. T. tricolorum and T. azureum were introduced into this country in 1828 and 1842 respectively.—J. MAYNE, *Eltham*.

VIBURNUM AND SPIRÆA.

SIR,—In Mr. Hillier's useful notes on Chinese shrubs (THE GARDEN, page 567), he describes the flowers of Viburnum Carlesii as opening before the leaves, which implies that, like V. fragrans, this species is deciduous. I suppose he has found it to be so, but on our mild west coast it retains its foliage throughout the winter, which greatly enhances the beauty of its pearly corymbs in spring. There is no shrub known to me with which amateurs have been more frequently disappointed owing to its being usually supplied grafted on our native wayfaring tree, V. lantana. The stock invariably pushes up vigorous shoots, and it requires constant vigilance to detect and remove them, the foliage of the two species being very similar in form, the only superficial difference being that the leaves of V. lantana are of a lighter colour than those of V. Carlesii.

Mr. Hillier mentions Spiræa Veitchii as one of the latest of the shrubby species to flower. It is past, however, before S. arborea has begun its display. That, at least, is our experience here. Mr. Hillier does well to praise S. arborea, for it is indeed the grandest of the genus and is not sufficiently well known as a woodland plant. I wonder whether he has found, as we have, that whereas S. arborea produces plenty of suckers as a means of propagation, S. Veitchii sends forth none.—HERBERT MAXWELL, *Monreith*.

WASPS AND DAHLIAS.

SIR,—I wonder if any of your readers have ever been troubled with wasps attacking their dahlias. I have grown them now for more than twenty years, and have never known it happen before this year. On returning home, after being away for a fortnight, I noticed that several of the dahlia plants were dying off, and was at a loss to account for it, until I noticed a number of wasps clustered roung the stem, close to the ground, and busily scraping off the bark, whether for food, or for some other purpose, I cannot say.

I did not know what to do to prevent them, but tried alum, so effective with slugs, and also painting the stems with cyanide of potassium, but the effect soon wore off, and they became as troublesome as ever; so eventually I wrapped the stems in fine wood shavings. This certainly prevented the wasps getting at the stems, though I noticed many of them trying to do so, but it was too late to save the plants, and all of those that had been attacked, gradually died off. Curiously enough the wasps did not attack the

Digitized by Google

young, upper branches of the plant, which one would have thought would be much softer and easier scraped, but only the bottom of the main stem, a few inches above the soil. Can any of your readers account for it?—G. ANSDELL, *Salisbury*.

ROSE GOLDEN EMBLEM.

SIR,—I wonder if my experience will be of any use to Mr. Younger. I have found the only way to get good bushes of Rose Golden Emblem is to leave them almost entirely unpruned. I do not know what the ultimate result of this treatment will be. At first I pruned them in spring, as with the hybrid teas, with the result that after pruning they died back almost to the ground. Also, when cutting for the house, I used to cut them with as much stem as possible, *i.e.*, back to the second or third bud. The result was the bushes made no growth at all, and at the end of the summer would only reach the height of 8ins. or 9ins.

Now, beyond cutting out dead wood, I have practically given up pruning, and when cutting the blooms I cut with only the soft stem, or possibly with one leaf, and float them in a black bowl. Sovereign is treated in the same way, and both of these are responding well to such treatment and are throwing up strong, new shoots.

The soil here is very light and sandy. Pig manure was used when making the beds, and a good deal of bone meal incorporated in the top spit. A little bone meal is worked in between the summer and autumn blooming.—GWENDOLYN ANLEY, *Woking*.

BUTTERFLIES AND MICHAELMAS DAISIES.

SIR,—Now that the Michaelmas daisies are at their loveliest, I am struck by the fact that this year they lack their usual adornment of butterflies. In my fifty-yard border of these flowers I could only find to-day one Red Admiral, two small Tortoiseshells and one Comma, whereas last year the two former species and Peacocks also were present in large numbers, several on each plant. The Comma is never plentiful with me, but on a day of sunshine it was generally possible to find half a dozen. I should much like to know whether other growers of starworts have to deplore a like absence of butterflies this autumn—units in place of hundreds—and possibly some entomologist reader can give the reason why the usual "crop" has failed. To me, the attraction which Michaelmas daisies afford for butterflies is one of their chief charms. The flowers are beautiful, of course, but when jewelled with butterflies they are a real joy to behold.—R. H., *Stratford-on-Avon*.

PERENNIAL LOBELIAS.

SIR,—I have just been reading, with great interest, the article in THE GARDEN of October 3rd on Perennial Lobelias. When at Vincent Square on September 8th I saw my old friend Mr. Jacob engaged in earnest conversation with Mr. Ladhams, and I hoped to see an article in THE GARDEN. I can endorse all he says about these lobelias, as I have grown them for many years. Mr. Ladhams advocates dividing them in the spring, but I have never done so: possibly I should get even better results. I grow mine in my bog garden; they are quite hardy and seem to revel in the damp position. I came home on September 9th and found them at their best. One large bed with Mrs. Humbert outside and Southampton in the centre was particularly good. I agree with Mr. Jacob about "B. Ladhams," but I miss the dark foliage of cardinalis. Carmineus is a beautiful colour, and also Rose Queen. I have not got Shirley Beauty nor any of the purples.—(Capt.) H. G. HAWKER, *South Devon*.

AN ENQUIRY.

SIR,—A lady going out to Egypt in January would be glad to know how she could make a garden to her house near Heliopolis.

What plants can she grow out there, and what annuals can she raise? Ought she to take roses and plants, etc., from England or France? She would have irrigation, and would be most grateful for any information.—A. B.

APPLE REV. W. WILKS.

SIR,—I noticed, in your issue of October 3rd, mention of an apple, Rev. W. Wilks, shown at the R.H.S. Show. It may be of interest to your readers that we managed to grow one here this year of the same variety, of the following dimensions: weight, 1lb. 5½oz.; girth, 1ft. 3½in.; eye to eye, 7¾ins., which seems a good size for outdoors in Scotland.—R. G. D. THOMAS, *Auldgirth*.

LIFTING AND STORING GLADIOLI

SOME of my readers may have grown gladioli for the first time this year, and although I am quite well aware many will be fully conversant with the terms "corms" and "bulblets," yet I venture to explain in detail, so that all may follow. I have been surprised many times during this autumn at the lack of knowledge respecting the culture of the gladiolus which enquiries have revealed, and this has led me to surmise that it is not generally realised how easy this fascinating flower is to grow.

The gladiolus may be raised from seeds, from corms and from bulblets. The amateur grower usually buys corms for the sake of quick results. If one plants top-size corms in the early spring, each one should normally produce, one, two and sometimes three flowering spikes. By October, it will be found that a new corm has formed at the base of every single spike of leaves which has been thrown up, just on the top of the old corm. Where only one flower spike has been produced, the new corm will normally be larger than the old, but where two or more new corms have formed on top of one old one, they will be smaller than the latter, but usually large enough to furnish good flowering stems the next season. All round the base of the new corm or corms will be discovered miniature corms, ranging from the size of a grape pip to that of a large culinary pea. These are generally termed "bulblets," but are also known under the names "cormels," "cormlets" and "spawn," and they may number anything from a dozen up to a hundred or two round each corm. Several conditions affect the actual number of bulblets produced, such as the "age" of the old corm, the particular variety, the method of cultivation, the soil on which they are grown and the season. Some varieties always produce twenty times the number of bulblets to others if conditions are the same in each case.

So much for what one may expect to find when lifting one's corms in the late autumn. As regards the actual lifting; this should be deferred until the end of October to enable the new corms to become fully matured. The operation should be done carefully, so as not to injure the corms, and it will be found a good plan to leave the bulblets attached to the corm as much as possible. Gently remove adhering soil and hang up the entire plants, root downward, in some frost-proof outhouse to dry, or lay them out thinly on trays. When they have somewhat dried off, cut off the leaves and stems about an inch above the new corms, and break the old shrivelled and useless corm from the bottoms. Then store both bulblets and new corms in a similar manner to which one stores apples, that is, in boxes or trays (potato chitting trays are admirable for the purpose), one layer only in each tray. Keep them in a frost-proof and airy place until spring, but any degree of warmth should be avoided or they will get too dry and hard. This delays growth later on, more especially in the case of the bulblets. I need hardly add that it is wise to take care to label correctly, and keep each variety separate.

Although many amateur growers may not have the convenience, or perhaps the patience, to save and grow on the bulblets until they reach top-flowering size, yet it is certainly rather a waste to destroy the new corms. The latter may not flower quite as early or produce as large a flower spike as a top-size corm, but in the majority of cases, will give a very fair flower stem and make a larger corm for the next season. This is taking good cultivation for granted. Of course, if the plants have not been well grown on fairly good soil, and if the cutting of the flower spikes has been carelessly done, one must not expect vigorous young corms. The leaves are the lungs of the plant, essential organs which, in like manner to daffodils and tulips, must be not cut off until the work of forming the new corm has been completed. It may be impossible to cut a good length of stem with the flowers, and not to injure the sword-like leaves tightly enveloping it in the slightest, but this injury may be minimised, as I hope to explain in a future article. Too often it is the practice to make a clean cut right through the leaves and stem within an inch or two of the ground level, and I should like to emphasise the point that this cannot possibly be done without greatly jeopardising the likelihood of a successful crop of blooms from the new corms the following season.

Size is not all-important by any means, and I should much prefer a medium-sized, plump young corm, to a larger, but flatter, specimen.

One has to wait a little longer for bulblets to mature, but with expensive varieties, it may be well worth while.

Digitized by Google

even to the amateur with little time or ground space at his or her disposal. Although they take almost as long to flower as do seeds, they have the distinct advantage of breeding true to type and colour (with the exception of an occasional " sport "), whereas seeds will give all colours. That is to say, bulblets saved from corms of Red Emperor will produce nothing but Red Emperor flowers, while seed saved from this variety may, and probably will, give numerous colours and shades, perhaps not one in the whole batch worth saving to grow again. It may not be out of place to indicate the correct treatment of bulblets. The best and quickest results may be obtained by sowing them in drills, one foot apart, as one would sow sweet pea seeds, on good, rich soil, soil that has been deeply dug and enriched with well decayed manure the previous autumn. Make the drills with a hoe 1in. deep in late February or early March, as soon as the ground is in a fit condition, and allow about an inch between each bulblet. Rake in a dressing of bone meal on top of the soil before making the drills. In many districts, unless some protection from frost is given for several weeks, there will be a serious risk in so early a planting, but this can be avoided by covering the entire surface of the soil with a layer of dead leaves or straw, with bushy sticks laid on top to prevent the wind blowing it away. Remove the straw as soon as all fear of frosts has passed. A moist soil is essential from the very first, and this can be maintained by watering in dry periods and continually keeping the surface loose with a hoe, but, of course, do not hoe deeply. The bulblets will be found to sprout or " germinate " unevenly, some throwing up their grass-like leaf blade very quickly, while others will remain dormant for weeks, months or even a year. Again, the bulblets of the various varieties behave very differently in this respect, some having the " dormant " tendency to a much greater degree than others. Needless to say, the bulblets should be kept free from weeds. A small percentage of those which first sprouted will bloom the first year, late in the season, but it is best to pinch or cut off flower spikes, as soon as they appear, to give the plant a better chance of making a good corm. Lift and store as advised for corms, and the majority will flower the following season. S.

PROPAGATION OF BEDDING PLANTS

THE time has arrived when the beds in close proximity to the dwelling-house will be cleared of their summer occupants, and replaced with plants that produce their flowers in the spring. In these days, however, the mixed border must not be forgotten : it ought to contain its due share of spring-flowering subjects, and here they look very attractive among the young foliage of the plants that carry on the display later on. Bulbs, especially the May-flowering tulips, play an important part in the scheme of spring bedding, also the narcissus ; but in these notes reference will be made to the plants that can be readily increased by division, seeds or cuttings. First and foremost are the wallflowers which are raised from seeds sown in May, and where this was done, and the seedlings transplanted a foot apart, a fine stock of bushy plants are ready for their final quarters. At the present time the varieties are so good that I prefer to see beds of wallflowers without any addition. A mixture of Orange Bedder and Fire King is excellent, and at a distance, with the sun shining on the flowers, they appear to be almost scarlet.

A well filled border or beds of polyanthus when in flower is a sight not soon forgotten, especially if it is shaded from the midday sun. These are increased both by division and seeds, the latter being sown either in the spring or autumn and given the shelter of a cold frame, although they will germinate freely in the open ground. When the seedlings are large enough they are put out in lines 1ft. apart, and here they remain until wanted for the beds. When it is desired to increase a special variety, division is resorted to, and this can either be done immediately after flowering or at the present time, when they are placed in the beds or borders.

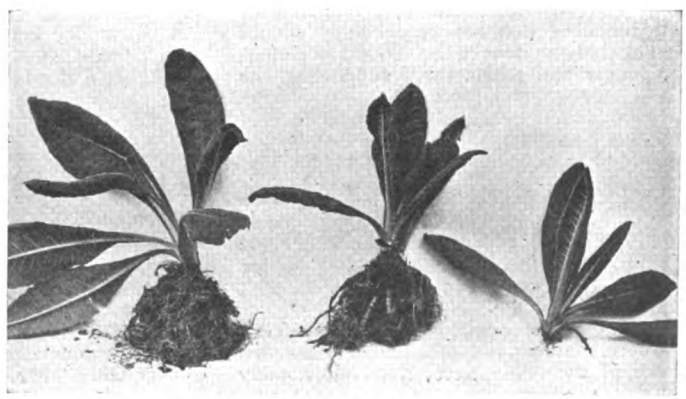
Where bulbs are grown in quantity, it is usually necessary to choose a small dwarf plant as the groundwork or carpet, and for yellow or white tulips the myosotis or forget-me-not is suitable. It is easily raised from seeds if sown in the open, but as a rule if a few odd plants are allowed to bloom in some out of the way spot, seedlings will appear in profusion. Arabis, particularly the double-flowering variety, is largely used in some gardens ; it is white, and in consequence it is available for a number of tulips and narcissus. It is propagated by means of cuttings, and if a few old plants are cut back after flowering a number of shoots will appear suitable for this purpose. They will form roots if placed in sandy soil in a cold frame and kept shaded from strong sunlight. Alyssum saxatile is another useful plant raised from seeds, which can be sown from March till May. It produces the most gorgeous, brilliant yellow effect. The aubrietias constitute quite a host in themselves, for they can be obtained in various shades from pale lilac and deep purple to crimson, although Dr. Mules is still one of the best. These are increased by cuttings and division. After flowering the plants are cut back, and the resultant new growths that will eventually appear can be utilised as cuttings similar to arabis. At the same time, the old plants may be divided and planted up in the reserve garden.

Violas are valuable for bedding purposes, and they are often employed as an edging to rose beds and borders, where they are very effective. Named varieties are increased by cuttings, and these can be inserted in sandy soil at this season, preferably in a cold frame. Select short-jointed shoots from near the base of the old plant, and often growths can be obtained with a few fresh roots attached. These readily establish themselves, and they should be removed to their final stations in the spring. In the meantime, keep them free from weeds, stir the soil occasionally, and admit plenty of air during open weather. Older plants that have been in the reserve garden may be lifted and placed in beds or employed as a groundwork for taller subjects.

Double daisies have come to the fore of late years, and they have proved most valuable for spring bedding, especially if beds are devoted entirely to them. Seeds should be sown in June, and the plants set out in the beds in October. They can be obtained in various colours, and choice varieties are increased by division after the flowering period.

Erysimum Golden Gem is a fine plant for spring bedding, being covered with its golden yellow flowers in early spring. Seeds should be sown early in the year, and the seedlings

THE METHOD TO BE ADOPTED IN THE DIVIDING OF HERBACEOUS PLANTS.



THE RESULT OF DIVISION.

grown on in the reserve garden. The various forms of primrose and the oxslip are often appreciated, and they will thrive in a partially shaded situation. Both can be increased by seeds and division.

A genus that should be represented in every garden is the pentstemon, and although they do not come within the range of spring bedding they can be mentioned, because now is a good time to insert cuttings. A cold frame is needed, and air must be admitted freely when roots are formed. T. W. B.

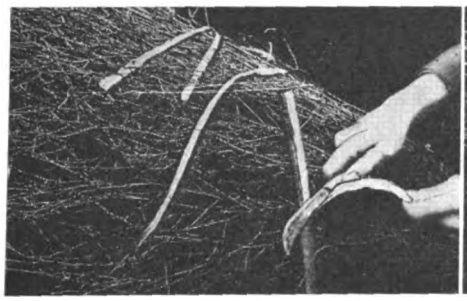
HOW TO MAKE A BIRCH BROOM

WHILE the fact may strike one that birch brooms are cheap enough without undertaking the bother of making them, there is the probability that many people are so situated that the knowledge of how to make a birch broom would be welcomed, possibly on account of the possession in quantity of the right kind of materials, and that it would provide employment for the gardening community at times when no outdoor work can be undertaken. There is but little skill required in order to make a passable and serviceable broom, and the tools are of the simplest order.

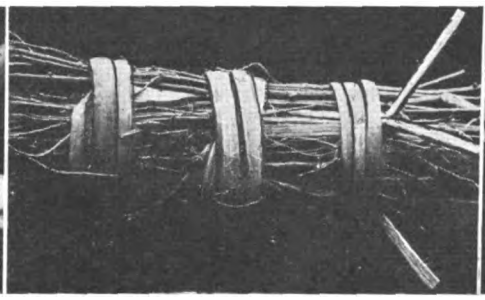
The materials required are, first, a supply of brushwood from the black birch, which is so plentiful in English hedges and woods, and some freshly cut hazel poles, which, again, present no difficulty to rural residents. Silver birch may be employed, but as its twigs are thinner and weaker, they do not make such a stiff broom as those of the black variety. Still, where a soft broom is required, one of silver birch is very useful, although it does not last very long. It will be realised, of course, that the professional broom-maker uses appliances that help him considerably in his work, but these need not be used by the amateur.

The birch twigs should be obtained from the woods during the winter and cut and trimmed into suitable lengths—from 2ft. to 2½ft. (or longer), according to the desired size of the broom. Both short and long twigs can be used; the end branches or side branches that are very twiggy should be selected, so that when bound together, the longer and stiffer twigs supporting the shorter ones, there will be a shapely and pliable mass of unbreakable twigs. The brushwood is sorted out and laid upon the ground branch by branch, all the while forming a symmetrical and even brush-head. This latter may be either pointed in shape or made perfectly level at the ends.

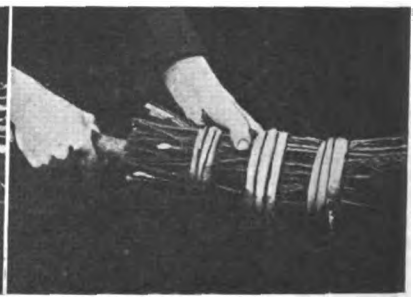
When a nice bundle has been made, procure a piece of rope (clothes line will be as good as any), and tie the bundle tightly, by means of a running noose that can be easily undone later on, one tie being made at the extreme end of the bundle, around the thick ends of the twigs, and another tie about half way towards the thin ends. Between these ties there is sufficient space to put on the permanent bands. These are strips of hazelwood with the bark on cut from a long, straight pole that has been freshly cut, the strip being about ¼in. in thickness or less, and from ½in. to ¾in. in width.



1.—MAKING THE BANDS.



2.—TYING AND BINDING THE TWIGS.



3.—FIXING THE HANDLE TO THE BROOM.

The process of binding is as follows. Take the birchwood bundle and, being seated, place it across the knees. Sharpen both ends of one of the hazel strips, and thrust one well into the bundle near the top or bottom cord tie. Now slowly turn the bundle round on the knees, meanwhile firmly pulling the strip perfectly tight as it winds around the twigs. When the other end of the strip has been reached, its sharpened point should be plunged into the bundle and drawn through the other side, the protruding end being cut off close to the bundle. Pull the band quite tightly and make a secure fastening.

A better way is to have a very long strip, give it three turns around the bundle, after forcing its end into the twigs, and then tuck the rest of the strip underneath the band, as shown in the second illustration, pulling it quite tightly and then allowing the free end to lie with the twigs of the bundle as though it were one of them. Then the next band can be put on a few inches down the bundle, binding it over the strip of the first band, its end being tucked in like that of the first band. A third band can then be wound round the bundle near the handle end in the same manner. This is clearly indicated in the illustration, the three strip ends, belonging to the three respective bands being clearly seen standing out from the bundle for that purpose. The three ties are far better than one or two, especially in the case of a large or heavy broom, which is the most serviceable.

In all cases the bands must be put on with a very firm hand, and the ends, whether forced through the bundle from one side to the other, or tucked in and incorporated with the twigs, must be made perfectly secure, otherwise they will not hold the broom together.

The handle has now to be fixed. This is sharpened at one end, and the operator taking the bundle in one hand, must force the handle into the midst of the twig ends, taking care that it is in the centre of the bundle. The handle can be rammed home to an extent that ensures a firm grip and no sign of looseness is observable. The cord around the bundle may be removed either before or after the handle is fixed. If the bands are firmly put on the cord may be removed as soon as the bands are finished.

H. A. DAY.

GARDEN TECHNIQUE

Notes on the Technical Side of the Garden and the Cultivation of Plants.

APPLES IN SCOTLAND.

IN general the apple and pear crop has been more or less of a failure this year. Some of the apple trees, however, notably Lord Grosvenor, have borne abundantly. The fruits of this variety vary greatly in shape, yet on the whole are easily identified. An old tree of King of the Pippins has also fruited well, while a tree of Worcester Pearmain on the trellis has borne bright and highly coloured fruits of a good size. James Grieve, Lord Suffield and a few others have also carried crops of fair-sized fruits.

It was noticed that fruits borne by a variety called Beauty of Kent became more highly coloured between August 22nd and September 4th. No doubt the changeable weather, with cold in the mornings and evenings, combined with showers and sunshine in the daytime, has had much to do with the coloration of the fruits. This, unfortunately, is not a dessert variety, but its colour, shape and size of the fruits would almost warrant it a place on the dessert table. Mr. Bunyard has stated that Beauty of Kent is "a most valuable and somewhat neglected variety." — DAVID ARMSTRONG.

BUSH FRUITS: TIMELY THINNING-OUT.

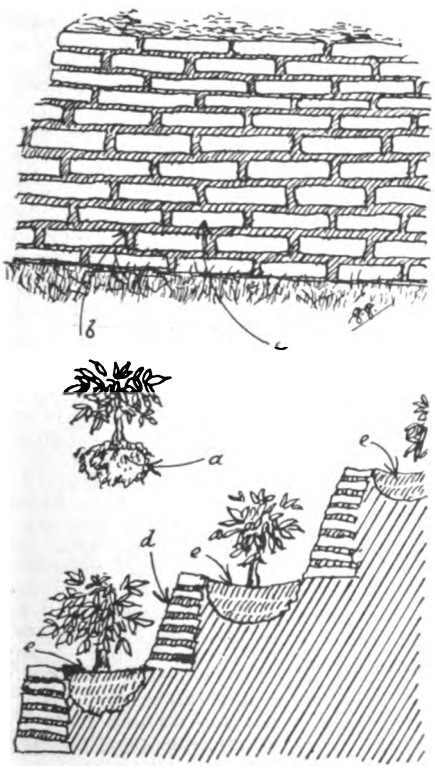
DIRECTLY any wood, young or old, is not required, it should be cut out and reduced to ashes in the garden fire. It should not be left on the ground or in heaps in some out of the way place, as the leaves and wood may harbour insect pests. If this unwanted wood is retained it does harm through helping to exhaust the strength of the tree and prevent the thorough ripening of the new growths, because its presence prevents light and air reaching the branches retained. Perhaps the wisest plan is to begin with the raspberries. First cut out all the old canes, those that have borne fruit; these are, of course, useless for another year, and the sooner they are got rid of the better for the canes retained. As a guide, I may say, allow a space of at least 4ins. between the canes—6ins. would be better still. To ensure this it may be necessary to cut out some of the smaller canes. Do not tie up the canes retained now: leave them as wide apart as possible for a time, then they will ripen better. Black currants should be dealt with next; as these bear fruit on the young wood, remove the older, especially that near the centre of each bush. Nice, pink-coloured buds may be seen on the lower parts of the branches that are to be cut back; these buds will grow freely next year and be very useful as fruit-bearing branches the year following.

Digitized by Google

Loganberries require similar attention to raspberries, but the branches retained should be much farther apart. Red and white currants and gooseberries may have branches cut out now to prevent overcrowding, the pruning proper being done at a later date.

FORMING AND PLANTING BANKS.

BANKS are objected to in some gardens, liked in others; they are necessary in some, quite unnecessary in others. Of course, a very unsightly bank may be made beautiful if it is properly dealt with. I recently had the pleasure of inspecting an Italian garden which was entirely surrounded by high banks; everything was very correctly done except the planting, or, rather, the placing of the shrubs and trees; these were much overcrowded. The idea was to create effect at once; this was secured, undoubtedly, but at the expense of the future. For four years or so the plants would improve—their general effect, too; then drastic thinning-out would be necessary, or the shrubs would spoil each other, and, unless the thinning-out was timely and done by an expert, the general effect would be marred for many years. This reference to planting for effect will be helpful to those who are inexperienced in the matter. Now, we will deal with the subject of bank construction. Plants bought from nurserymen are generally well prepared for removal, as they have been duly lifted and replanted, possessing a lot of fibrous roots, compact, as seen at *a* in the sketch. Looking at the front of the new bank, we see that the joints, *b*, of one row of retaining turves come in the centres of the next row of turves—in the same way as bricks are laid. A sectional view of the bank shows, at *d*, a slight incline of each sustaining wall of turves; this gives added strength and durability. At *e*, *e*, *e*, some prepared soil should be placed



for the benefit of the new plants; this is especially necessary where the original soil is of poor quality.—G. G.

PEAT AS MANURE.

BOTH light and heavy soils need the addition of humus or organic matter, the former requiring not only to be enriched by it chemically, but also to be rendered more compact by its physical properties, and so less liable to lose by too rapid drainage the available plant food which it contains. Sandy soils are light in colour as well as in body. The darker a soil is the longer is it able to retain the sun's heat, and so the addition of humus, by darkening them, adds to the natural warmth of sandy soils.

Heavy marls and clays require the addition of humus for this reason, as without it they retain moisture for so long and in such quantity that in the winter and during wet seasons they are too cold to be fertile. In summer they lose moisture by evaporation and become baked and useless for plant life. If humus is generously added every year to these heavy soils these disadvantages are mitigated and finally overcome. Moreover, its presence in the soil releases the locked-up supplies of plant food which are in clay soils, and renders them constantly available for the plants.

Every horticultural student knows that the best way of adding humus to the soil is by incorporating farmyard manure with it. It is, however, becoming increasingly difficult to obtain farmyard manure for private gardens and nurseries, as the farmers need it all for their own use.

In France, natural manure is used in greater quantities than in England, on account of there being so much intensive culture in the market gardens of that country, and also because, in those parts of France which possess a Continental climate, and also in southern France, shrubberies, flower beds and massifs (beds of mixed shrubs and flowers) are mulched with a thick layer of half-rotted manure to retain the moisture. In those regions the summer sun burns and dries up the soil in a manner which is unknown in Britain. The ground is watered copiously when the mulch is applied and at regular intervals afterwards from May to October. For this mulching horse manure has been chiefly used, as it was also used in great quantities for general purposes of manuring of crops.

Now that motor cars, lorries and traction engines have almost ousted horses, and farmers will not sell their farmyard manure, the manuring of gardens of all kinds has become a serious problem in France. In the east and central east of that country, where the soil is practically pure limestone, as the names of the Departments of Marne and Haute-Marne indicate, the question of increasing the fertility of the soil is always an anxious one.

During the past few years specialists have been at work in the market gardens of those regions testing the fertilising power of peat, with a view to using it to replace farmyard and horse manures.

Peat, being pure humus, is consequently solely a nitrogenous manure, though its physical properties add to the colour and density of the soil.

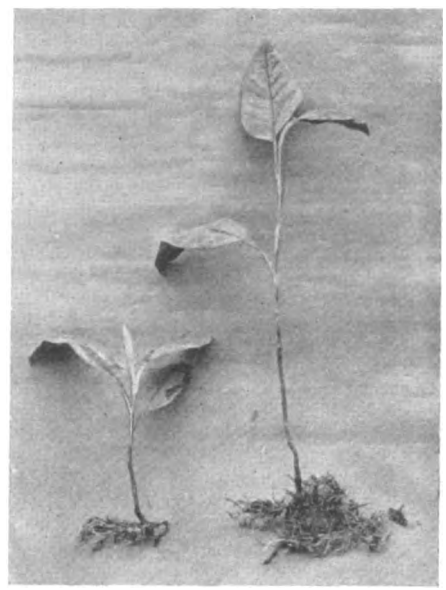
To bring about the nitrification essential to render the nitrogen in peat available for the plants, it is, of course, necessary that the soil should contain lime in sufficient quantity (hence the choice of the limestone districts for experimenting with peat).

The French agricultural chemists assert that the results of their experiments have proved that peat *alone* has no chemical effect on the soil, but if it is incorporated with a compost it produces *better* results than farmyard manure, and, like it, continues to undergo nitrification in the second year after its application. In districts where peat is easily obtainable it would be well worth while for gardeners to add it to their rubbish pit, where vegetable and household refuse, green fibrous-rooted weeds, lawn mowings and rabbit and poultry manures will supply additional nitrogen, and bones, woollen rags and old leather the necessary phosphates.

Potash, the third essential element for plant food, can be obtained from the wood ash of the bonfire where such weeds as docks, thistles, convolvulus, ground elder and couch-grass and cotton rags, papers, lumps of clay and prunings have been burnt.—VICTORIA SLADE, *Godalming*.

MAGNOLIAS FROM CUTTINGS.

ALTHOUGH it is generally laid down that propagation of magnolias is best effected by seeds, layering and, occasionally, grafting,



From left to right: A THREE WEEKS OLD CUTTING OF M. WILSONII; A HEALTHY PLANT OF M. PAVRIFLORA FROM A YEAR-OLD CUTTING.

readers of THE GARDEN may be interested to learn that certain species of this beautiful genus can be successfully propagated from cuttings. These are best made in July and August from the current year's wood and inserted in sand in a close propagating frame with a gentle bottom heat, where, it will be found, they root in time to become established before winter sets in.

Last year best results were obtained from cuttings of MM. Wilsonii and parviflora. These rooted quickly and have now developed into healthy young plants. Cuttings of M. conspicua var. elongata took longer to root and failed to establish themselves after potting, and only a small percentage survived the winter.

This year several species are being tried, and results, so far, are as follows: Cuttings of M. Wilsonii inserted on August 21st made quite a mass of roots and were potted up on September 13th; while a few cuttings of M. salicifolia inserted in July have rooted and appear to have become established in their pots.

Cuttings of MM. conspicua var. elongata, parviflora, Veitchii, Nicholsoniana, Dawsoniana, Sargentiana and Watsonii have callused over, and, with the exception of Dawsoniana and Sargentiana, they all look promising.

One curious point to be noticed in the propagation of some magnolias is that shoots which touch the ground when a branch is being layered will, if taken as cuttings, root readily. Last spring, when shifting a plant of M. Nicholsoniana, a cutting was taken from a small branch that had been sweeping the ground, and within a fortnight it formed quite a number of roots, and has grown freely throughout the summer.

Particular care is required when potting up the rooted cuttings, as the roots of magnolias are very easily injured.—F. P. K

AUTUMN WITH OUR ROSES.

NOW that the rose planting season is upon us, the majority of rosarians are considering the purchase of new roses and of the preparation of beds to accommodate the new arrivals. This, undoubtedly, is wise, but there is a most important cultural item which deserves every attention, and that is, the ripening of the shoots of the established roses. The majority of people do not realise how important this fact is. All weak growths should be cut out from the base in order to let in sunlight and to permit of a free circulation of air about the shoots which are retained. This may be done by the placing of bamboo canes at suitable points in the bush, which will ensure the growths being perfectly ripened, and the roses next year will be all the finer for the trouble which is taken now. The roots should never be allowed to become dry during the winter months. Rather must they be kept in a moist condition. To allow a plant to become dry at the roots interferes seriously with its growth the following year and poor roses are the consequence. A dressing of the purest lime to keep the soil sweet and of steamed bone flour to encourage root formation can be given to the rose beds this month, and will complete their requirements and ensure a grand display of bloom next summer.—C. A. JARDINE.

PARSLEY, MINT AND THYME IN WINTER: STORED HERBS.

HERBS are always useful in the garden and dwelling-house, but they are much neglected in many gardens while growing and after they are gathered. The mint and thyme beds are often found to be full of weeds, which rob the plants of much nutriment. As both kinds of herbs generally remain undisturbed for a considerable time, more care is needed, in their case, in dealing with them, so that weeds will not gain the better of the legitimate occupants. If new beds are to be formed during the autumn, winter or spring, it would be labour well directed in thoroughly cleaning the soil first. This may mean deep digging; if so, the plants will benefit. A very rich soil is not required, a moderately rich one will do quite well and the plants will retain good normal health longer in such. Herbs are at full strength when they reach the flowering stage. If, however, the soil is very poor, the annual growth is correspondingly weak and there is not much besides puny flower spikes to gather and store. The rhizomes of mint should be laid in the soil at least 1ft. apart to allow for the spread and increase of these roots in due course. The bed should be several feet in width to avoid the growth of mint on paths; hand weeding is always the most satisfactory. Thyme should be thoroughly cleaned now, leaves and all foreign matter removed from beneath the spreading shoots. Parsley, if young, should be finally thinned as sturdy plants are more profitable than overcrowded weakly ones. It is well now to make provision for any necessary protection. Stored herbs are cleaner if covered with sheets of paper.—HANTS.

THE WINTER CARE OF SEEDS

THERE is a particular satisfaction, and indeed fascination, in saving seeds of a favourite plant and endeavouring to raise young plants from those seeds. The amount of success that will be achieved next season depends in no small measure upon where and how the seeds are kept until sowing time arrives in early spring.

The vitality of the germ of life in seeds varies to an extraordinary degree, and while some seeds may remain dormant for several years without apparent effect upon their germinating power there are many that become rapidly weaker, and practically useless before they are two years old. In the case of the more vigorous seeds it may be of little importance where and how they are stored between the time of harvesting in autumn and sowing in spring; but with such as are of fleeting vitality proper care and storage during winter makes a very considerable difference.

It may be taken as a general rule—although, as with most rules, there are a few possible exceptions,—that when seed has thoroughly ripened and dried it is best removed from its pod or husk. Up to a certain point very many seeds draw some nourishment from the pods or capsules in which they are contained, but when they have filled their cells with necessary moisture and nourishment they should properly become quite inactive and dormant until they enter the soil. The pods and husks, however, have, generally speaking, considerable life left in them for some time after the seed is ripened, and if put away in a dry place the moisture gradually evaporates, and as this goes on the pod will draw moisture through the porous skin or shell of any seed that touches it. Contrary to popular opinion, therefore, the natural seed vessel is by no means the best protector of stored seeds.

Equally bad, and in some cases worse, are bags or packets made of rough-surfaced, absorbent paper. Seedsmen of good standing who are obliged to keep many seeds in paper packets are careful to use a hard, glazed-surfaced paper; but in the case of many of the cheap packets of seeds handled by dealers with little technical knowledge the packets are made of cheap, inferior paper, and that is one among various reasons why low-priced seeds are not always cheap in the truest sense.

Better than paper of any description are small tins with tightly fitting lids, provided they are clean and have contained nothing of an injurious nature. Many of the choicest seeds, such as begonia, orchid, gloxinia, etc., are kept by growers and merchants in glass bottles with tightly fitted stoppers, and where one has a small quantity of seed to take special care of it is worth while bottling it.

A dark store cupboard where a cool but even temperature is maintained is best. It is an error of judgment to keep seeds near a fireside to ensure dryness, for while damp must, of course, be avoided, a high temperature is also disastrous. Mischief is sometimes done by placing seeds in bottles on a shelf where the sun, shining through a window, can reach them. Even in the winter, bright subshine is capable of heating the air inside a bottle much to the detriment of any seed. No seeds require light while stored; a cupboard is, therefore, the best place; or they may be kept in a closed box or drawer. L. A.

Sale at Messrs. Clarence Elliott's Nurseries, Stevenage.—On September 30th last a sale of plants was held at Messrs. Clarence Elliott's Nurseries, Stevenage, by Messrs. Protheroe and Morris of Cheapside. This proved to be remarkably popular, the attendance being so great and the commissions received so numerous that not all would-be customers could be supplied. Specially keen was the competition for the dwarf shrubs, of which large numbers of five kinds were included, but these proved to be insufficient to meet the demand. Rock and alpine plants, including many rare varieties and several novelties, met a ready sale, as well as the popular herbaceous plants, including asters, peonies and delphiniums. There were over 700 lots catalogued, but about twice that number were actually disposed of.

CATALOGUES RECEIVED.

The Constructional Engineering Co., Limited, Birmingham, send us pamphlet No. 138, giving particulars of the Titan steel barrow, which they are at present manufacturing. Such a barrow seems eminently suited for use in all large gardens and will prove much more serviceable than the old wooden type. This firm supply a variety of types, each of which has its particular uses. The prices do not compare unfavourably with wooden barrows of similar capacity.

Messrs. David Green and Son, Lytham, Lancs.—A catalogue for the handyman, at least one item of interest to gardeners is the wire cord which is offered. This wire can be readily employed in the tying up of plants, and for training peas, beans, etc., and for many other purposes in the garden it will be found admirable.

Mr. R. C. Notcutt, Woodbridge.—An extensive list of nursery stock, including fruit trees, shrubs and trees, alpines and general herbaceous. A wide selection is offered in all sections and especially in shrubs. The catalogue is illustrated by many excellent half tones, which bring out the character and beauty of the plants shown. Gardeners should procure a copy for reference purposes.

THE 'PATTISSON' HORSE (LAWN) BOOTS

"The ONLY Economical Ones."

USED in the Royal and Thousands of the Principal Gardens, GOLF and CRICKET GROUNDS, and exclusively at the Oval (S.C.C.C.) for the past 20 years.

OVER 10,000 SETS USED IN THE U.K.

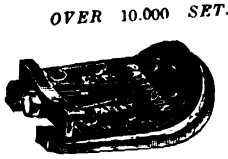

Fig. 1 for Shod Horses.

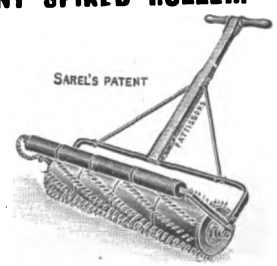
Fig. 2. Welted Boot.

HUNDREDS OF TESTIMONIALS.

The Field says: "As good as anything that could be devised." Mr. Wm. Hardy (Gardener to Lt.-Col. Hon. W. Guinness): "The boots supplied 17 years ago are still in use and have always been satisfactory."

SAREL'S PATENT SPIKED ROLLER.

COMM. HILLYARD, R.N., The All England Lawn Tennis Club, Wimbledon, writes: "The 'Sarel' Roller is invaluable for aerating the ground. It saves an enormous amount of labour and is most beneficial to the turf. I should be very sorry to be without such a valuable implement."



H. PATTISSON & CO., Streatham, London, S.W.16

Entered as Second-class Matter at the New York, N.Y., Post Office.

CURIOUS PLANTS

I HAVE bought some new toys which give me a great deal of amusement. They are succulents, not the juicy, gross creatures of our gardens, such as sedums and sempervivums, but those curious things which, we are told, live in places like Mexico and the Kalahari Desert in South Africa, where a few drops of rain dribble on them once a year or so. I had heard of people getting succulentiasis, or the craving for cacti and their weird relations, but I had looked upon them with pity, as I do unfortunate mortals who produce trays filled with broken rock or rows upon rows of preserved spiders.

In my own defence I must say that my attraction towards them has been gradual and perfectly logical. I like seeing living plants about me. I live in a flat, where the air is dry, and it is moderately warm. I have tried bulbs and various other plants in pots, but they dislike my climate and refuse to grow satisfactorily. Somebody told me that cacti would love my conditions. Apparently they do, and so I have a tray filled with curious-looking individuals that are like nothing else on earth.

Being entirely ignorant of their names, as well as of their interior economy, a stand at a recent show was so attractive that an order was given there and then, for it is only after seeing a collection that the ignoramus can pick and choose between the dozens of species and varieties. Now that they have arrived and have been leisurely examined during the past ten days, I can feel the fascination of them growing upon me. They are such sturdy, dumpy, ferocious looking inanimate objects. They arouse my curiosity. Why should one grow a beard out of the top of its head? Why should another look like a furry caterpillar with a pain? I can understand the fur, but why the serpentine twistings? Above all, why should these plants be christened with such terrible names? The names of Temperate Zone plants are bad enough, but these are dreadful. Perhaps their finders swore a solemn oath that they would get even with them for the discomforts of desert travel. If so, their revenge has been perfect.

The only one that has any pretence to beauty is a little plant that looks like a tiny aloe, called Haworthia verruculata, which has bright green leaves banded on the outer side with wavy ribs of waxy white. It is about 2ins. high and is very attractive. Then there is a creature called Stapelia mutabilis var., which sends up quadrangular spikes armed with hooks. The colour varies from green to the pinky-fawn of a well nourished slug. This is about 8ins. tall and is the giant among my pygmies. I am not sure that I like it; the fleshy spikes appear to have the same consistency as a pig's foot hung in a butcher's window. Next on the list is Pilocereus Daukwilzii, a species of old man's beard which is obviously ashamed of its nakedness and covers itself with hairs, dark brown on the body, cream-coloured on the top. This is an unsociable plant, for I began to barber its hair with my fingers and found that it was also armed with sharp spines under the hair; but I like it; it is what booksellers' catalogues would call "curious." One of the oddest has been christened Echinocactus minusculus. It is like a round green button with a concave top. It is covered all over with little fawn excrescences each with a little crop of stiff hairs sticking out. This is the most inanimate looking of all.

My tastes, apparently, run towards mamillarias, for I have a number of them, including the aforesaid caterpillar. The most formidable is not satisfied with defensive spines sticking out from what look like little green bulblets with a wadge of white cotton-wool between each, but has a name that would repel all marauders if it was as defenceless as an infant. It is called Mamillaria centricirrha. It must be a succulent morsel to make it form such defensive and ferocious prickles. The pigmy of the collection is M. Bocasana, a little round green ball covered with what look like dandelion seeds. Then there is one which is indescribable, called M. camptotricha. It is like an "old man's beard," with long spikes in process of turning into hairs. It is vaguely reminiscent of a sea urchin and also of a dish—I believe called a Kromeski—which is meat rolled in the finest of spaghetti and then fried. But this description is becoming involved, and I must stop.

These are fascinating plants and, I am told, flower in due course, and very pretty flowers too. They also have the advantage of doing best when left alone. It makes little difference if you forget their weekly watering, and they dislike re-potting. Such accommodating plants are so useful for a living-room. I feel an attack of succulentiasis coming on.

E. H. M. C.

OUR NEXT ISSUE IS THE SPECIAL AUTUMN PLANTING NUMBER WITH A COLOURED COVER.

PLEASE REMEMBER TO TELL OTHERS ABOUT YOUR PLANTS THROUGH THE COLUMNS OF "THE GARDEN."

GROW MORE ARBUTUS

BY W. J. BEAN.

IT is rather remarkable how much this genus of evergreens is neglected in gardens situated where the climate is of average mildness. In the warmest counties of the west and south the choice of flowering evergreens is, of course, much greater than it is in the home counties and farther north, where, as a matter of fact, evergreens of the same character as the arbutuses are not plentiful. If we exclude the rhododendrons, the Portugal and cherry laurels, how many are there left which grow 15ft. high and upwards that possess so many attractions? Scarcely one I will venture to say.

Then, apart from their flowers and fruit and the rich green of their foliage, the arbutuses have one great additional charm—not present in many shrubs or trees—in the frequently beautiful colouring of the trunk and limbs, which, when old enough, assume terra-cotta or cinnamon hues. In large trees this may even be regarded as a chief attraction.

Why, then, are the arbutuses so scarce? Chiefly, I think, because they are not easy to transplant; few shrubs, indeed, are more affected by root disturbance. They are not adapted for the ordinary routine of nursery practice, *i.e.*, put out in rows or plots and transplanted occasionally until of saleable size. They must either be planted in permanent places while they are quite small, or grown on in pots, or transplanted with a considerable amount of soil firmly attached to the roots. Pot culture is the safest, but one has to guard against the plants becoming pot-bound, a state which induces a coiled formation of the roots and is likely to interfere with their subsequent development after being planted out.

Arbutuses do not seem very particular as to soil. They succeed well in sandy peat or light loam, and the commonest, A. Unedo, sometimes grows naturally in limestone formations, but I do not know about the others. The late Mr. H. J. Elwes stated, from his experience I suppose at Colesborne, that A. Andrachne "seems to enjoy lime in the soil." If that be so, then it will apply equally well to A. hybrida, which is a cross between that species and A. Unedo.

AN OLD TREE OF ARBUTUS ANDRACHNE AT MARCHMONT.

Arbutuses should be raised from seed whenever possible. In regard to A. Unedo, this is not difficult to obtain at home, for this species produces fruit fairly regularly, often in great abundance. Seed of A. Menziesii is usually included in the catalogues of leading American seedsmen. A. hybrida does not seem to ripen seed very easily and, along with its various forms is usually grafted on seedlings of A. Unedo.

Seeds should be sown in early spring in a cool or slightly heated frame or greenhouse. A little artificial heat will hasten germination. The seed, like that of most of the heath family, is small, and except for a slight sprinkling of sand should be on the surface of the soil, the upper layer of which, as for rhododendrons, should be finely sifted. As soon as the seedlings are large enough to handle, they must be pricked off about 2ins. apart into shallow boxes or pans. When 2ins. or 3ins. high, they can be put singly into pots and, when large enough, shifted into those of larger size. Plants in 6in. or 7in. pots should be large enough to put out in permanent places. If this early pot culture is not possible and the seedlings are planted in the open ground, care must be taken when transplanting to carry a "ball" of earth with them. With a transplanting machine or other apparatus for keeping the "ball" of earth intact, bushes up to 8ft. or 10ft. in height can be removed safely, as is frequently done at Kew.

So far as I have seen the arbutuses like plenty of sunshine. They grow quite well in moderate shade, as one may see them in the pine plantations at Bournemouth, but in such places they are frequently loose or even lanky in habit and do not flower or bear fruit so freely as in sunnier sites. I remember that on the coast and islands on the Dalmatian side of the Adriatic, where the summer sun is much hotter than we ever experience, A. Unedo grows fully in the open.

ARBUTUS ANDRACHNE.

There are a few examples of this speces at Kew from 10ft. to 15ft. high, but it is scarce in this country. I do not know of any nursery catalogue in which it is offered. Perhaps the best specimen in England is in the Botanic Garden at Bath; there is also a good one at Westonbirt. The bark on old trees becomes smooth and of a beautiful brownish red. The leaves are oval, considerably larger than those of A. Unedo, from which, as well as from A. hybrida, they differ (at least in the adult state) in having no marginal teeth. The flowers are dullish white, pitcher-shaped, ¼in. long, produced during spring in terminal panicles 2ins. to 4ins. long. I have not seen fruit developed in this country, but as one sees it in South Europe it is globose, orange-red and half an inch long, slightly rough, but much less so than that of A. Unedo. It is difficult to say why this species should be so much more uncommon than A. hybrida, as it was introduced more than two hundred years ago and in the south of England is quite hardy.

A. HYBRIDA. SYN. A. ANDRACHNOIDES.

Next to A. Unedo this is the commonest of the arbutuses in gardens, but in recent years it has become difficult to acquire. It is one of the shrubs which brings home to us how much we lost by the passing of the Coombe Wood Nursery, for they used to stock it and several of its forms there. These have been grown under various names, such as magnifica, photinæfolia and Rollisonii, representing superior or varying forms. Being a hybrid between Andrachne and Unedo, it naturally varies to some extent, although it is usually about intermediate between its parents. Its flowers are white and ¼in. long, opening in panicles both in autumn and spring. It can always be distinguished from Andrachne by the invariably toothed leaves and the glandular downy young shoots. From A. Unedo it differs in its larger leaves, smaller, less roughened fruits and by flowering partially in spring. The form known as Rollisonii is a good one, distinguished by its fine foliage.

A. hybrida is said to have originated in Osborn's nursery at Fulham about 1800, but that I should say is very doubtful. It is more likely to have been introduced, perhaps by seeds thought to be those of A. Andrachne, from Greece.

A. MENZIESII, THE MADRONA.

This Californian tree is not only the finest of the arbutuses, but the noblest of all the heath family. A few years ago

THE FLOWERS AND FRUITS OF THE STRAWBERRY TREE.

Mr. F. R. S. Balfour of Dawyck showed me photographs he had had taken of a tree growing in the Marin county of that State, which had a short trunk girthing over 20ft. Drawn up by association with tall conifers, it is sometimes 100ft. high. It is, however, more handsome in the open where it forms a huge rounded head of branches. As in A. Andrachne, the leaves of adult trees are mostly without teeth, although on young plants or very vigorous shoots they are quite frequently toothed. Of oval outline and up to 5ins. or 6ins. in length, they are of a glossy, slightly metallic green above and glaucous beneath, much more glaucous than in any of these hardy species. The flowers open in April and May on terminal, erect, pyramidal panicles, being dull white, almost globose and fragrant. The fruits are orange red and about the size of a large pea. Among the arbutuses this is unsurpassed in its rich leafiness and the fine terra-cotta hue of its limbs and trunk. In a young state it grows vigorously and often so late in the season that the sappy, unripened tips are liable to be cut back by winter cold. Otherwise it is perfectly hardy. A specimen near King William's Temple at Kew raised from seed in 1894 is now nearly 30ft. high, its trunk 3ft. 8ins. in circumference. It cannot, therefore, be called slow growing.

A. UNEDO, THE STRAWBERRY TREE.

This is the only arbutus to be found in nurserymen's catalogues in general, but occasionally forms of A. hybrida are offered also. Although in the neighbourhood of the Killarney Lakes, where A. Unedo grows wild, it is occasionally a tree 25ft. to 30ft. high, one finds it usually in gardens as a bushy shrub of rounded shapely form. It has smaller leaves than any other of the hardy sorts, and they are usually 2ins. to 3ins. long, half as much in width, often broadest at the terminal half and always toothed. A good distinguishing character of the species is furnished by the numerous gland-tipped hairs on the young shoots. They occur also on A. hybrida (inherited from this species) but are much less abundant; on A. Andrachne and Menziesii they do not occur at all. The flowers are of the typical size and shape, and come in drooping panicles in autumn, being of a rather transparent white, sometimes tinted with pink. As an ornamental fruit-bearer this is by far the most attractive of these hardy species, the berries being ¾in. wide, brilliant orange red and roughened by excrescences on the surface.

VAR. RUBRA (or Croomei) is one of the prettiest forms, the flowers being of a very pleasing deep pink hue. It used to be grown in the Coombe Wood nursery, but is now uncommon, although a fine bush of it in the Kew collection is now laden with blossom.

VAR. INTEGERRIMA has leaves with no marginal teeth, while var. quercifolia has them deeply toothed; var. compacta makes a neat low bush with small leaves. None of these varieties is equal in merit to the type or the var. rubra.

Besides being wild in Ireland, A. Unedo is spread widely over south Europe from Spain to Greece; it occurs wild also in Asia Minor, Syria and North Africa. It has been stated that it was introduced to Ireland in the sixth century by the monks of the abbey of St. Finian, situated on the shores of Killarney. This has not been accepted by botanists in general, and the late Professor Babington maintained that the idea was inconceivable, as the tree was to be found in isolated spots, far up the mountains. I do not see that this is at all conclusive, because birds, which eat the fruits, might drop the seeds in all sorts of out-of-the-way places, assuming, of course, that they are able to retain their vitality after passing through the bodies of birds.

PANSIES AND VIOLAS

DURING recent years these pretty and useful flowers have been much improved. They are admirable for bedding purposes or for edgings along herbaceous borders, and they may be used with advantage in the rock garden.

Now is the time to insert cuttings which will produce sturdy plants in the spring ready for planting out in March or April. As long as the weather is open, cuttings may be taken till almost the end of the year, but the sooner they are put in the better, as they require four or five months to make strong roots.

A cold frame is the best receptacle for the cuttings, but I have used ordinary margarine boxes covered with sheets of glass, and if these are packed close together in a sheltered part of the garden they are practically frost-proof. In very severe weather they may be removed to a greenhouse if the cuttings are from scarce varieties.

VIOLAS FOR EXHIBITION, IN THE GARDEN OF MR. H. J. MILNER.
Winner of the Clay Perpetual Challenge Trophy in 1925.

Digitized by Google

MAKING A COMPOST FOR THE CUTTINGS.

If the ordinary garden soil is of a light nature the cuttings will root readily in this if a little sand is added. A good mixture can be made from soil found in the hedgerows, which usually contains a good proportion of leaf-mould. A little well rotted manure may be added, and also a sprinkling of sand. All cuttings root more readily if a little sand is dropped into the hole where the base of the cutting rests.

SELECTING THE CUTTINGS.

Basal cuttings are the best, and these should be selected whenever possible. The longer growths, some of which may have borne flowers, need not be discarded in the case of rarer kinds, but all hollow cuttings should be thrown away. The cuttings should be 2ins. or 3ins. in length. Sever them just below a joint and remove all lower leaves. Trim off any that are damaged or decayed. Press them into the soil firmly and sprinkle a little sand between them. This helps to prevent damping off. Keep them fairly close for a week or two, afterwards giving ventilation on favourable days. In spring remove the lights when all fear of frost is past and gradually harden off before planting out.

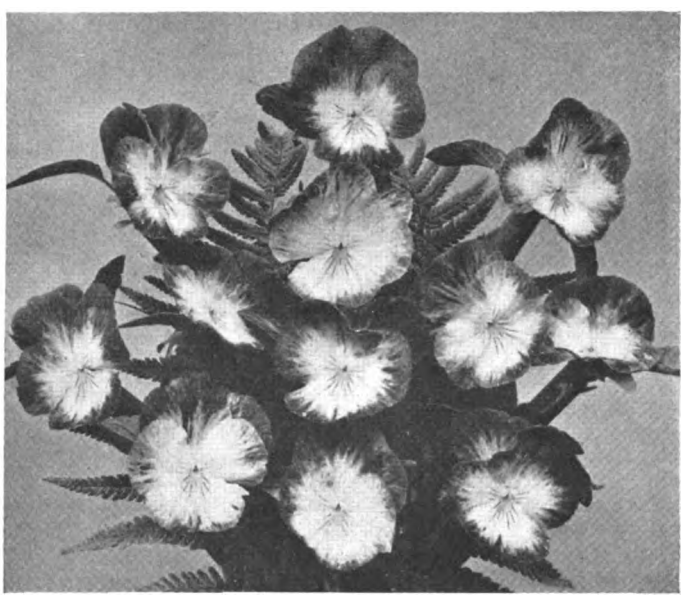
PANSIES.

The fancy pansy is most popular, and there is now a wide selection of varieties. The following would make a good collection for the beginner: Mrs. Andrew Frater, Mary Drummond, Annie Beveridge, Alexander Lister, Mrs. A. B. Cochrane, Jean Lister McKellar, Mrs. A. Paul, Nellie Cochrane, John Greig, Dr. Kelso, Miss N. Thomson and Susan Milligan.

There are a number of good bedding pansies. These are more compact in habit than the larger flowered kinds and they are more floriferous. One of the best is Bellfield, an ox-blood self of very rich colouring. This variety was raised and introduced by Messrs. Dobbie and Co.

VIOLAS.

Roughly, the violas may be divided into three groups: (1) the large-flowered kind that are exclusively used for exhibition and which have a somewhat "leggy" habit; (2) the large-flowered kind that have a tufty habit, and which may be used for bedding purposes or garden decoration, especially if grown as two year old plants; and (3) the purely bedding type. The latter are recommended for bedding or edging. They have a very tufty habit, strong growth, and, as a rule, are free-flowering. A large stock of these can soon be worked up, as they give plenty of cuttings each year.



MRS. CHICHESTER, A CHOICE BEDDING VARIETY.

The following is an up-to-date selection of bedding varieties: Swan (white), Maggie Mott (pale mauve), John Quarton (soft mauve), Mauve Radiance (deep mauve with a glossy sheen), Royal Sovereign (rich yellow), Lady Knox (cream), Jubilee (deep purple), Archie Grant Improved (deep indigo), James Pilling (white, edged with lavender), Mrs. J. Scalley (white, edged with blue), Master Bankes (lemon yellow), Tangerine (orange), Pride of Darras (white with a deep band of purple) and Mrs. Chichester (white centre, edged and flaked mauve).

The well known Moseley Perfection is a large-flowered type that can be used as a bedder, and it is very hardy, thus making a fine plant the second season. Other good varieties of this type are Mrs. J. Smith (white, suffused with lilac), Mrs. J. Fisher (cream ground, flushed and suffused with bluish purple) and Mrs. W. R. Milligan (white with edge of delicate pale blue).

An excellent selection of exhibition violas might include William Barr (white), Mrs. Andrew Stevenson (golden yellow with a broad band of bluish heliotrope), Kathleen Condry (purple) Rowan Hood (chrome yellow, belted with lavender), Jean Cowan (chrome yellow edged with pale lavender), John Adamson (orange yellow), Agnes Brown (glossy black with light lavender-blue top petals), Mrs. William Boyes (lemon yellow edged with lavender), Peggy Ramsey (cream suffused heliotrope), Moseley Ideal (pale yellow edged with mauve) and Mrs. H. J. Milner (white, edged with bluish heliotrope). The two last-named are 1926 novelties. Both are very beautiful flowers and useful either for exhibition or garden decoration.

NORMAN LAMBERT.

AUTUMN PRUNING OF SHRUBS

IN comparatively few gardens is sufficient attention given to the pruning of shrubs. If they are to attain their full value as decorative subjects, shapely specimens, attractive in foliage and flower, the pruning and regulating of their growth is as desirable as the pruning and thinning of fruit trees.

There is considerable variation in the treatment necessary with a present-day representative collection of hardy ornamental flowering and foliage shrubs. For the purpose under consideration, however, it is fairly easy to divide them into three main groups:

(*a*) Those which flower on the new growths of the season and which are best pruned before new shoots show signs of development in spring Good examples are Buddleia variabilis, varieties of Spiræa ponica and Hydrangea paniculata.

(*b*) Those which flower on the growths the previous year before mid-summer and, if pruned immediately after flowering, have time to make and mature new wood by the autumn. Included in this group are forsythias, Prunus triloba flore pleno and Philadelphus Lemoinei erectus.

(*c*) This is the largest group, as it includes two distinct classes—(1) those which flower in spring and early summer and produce ornamental fruits, *e.g.*, the wild roses, many barberries and the cotoneasters. Nothing can be done to these, obviously, until the fruiting period is over. (2) Those which flower on the previous season's growths, but develop new shoots about the same time. Examples are the new Buddleia alternifolia, Spiræa canescens and the majority of the philadelphuses.

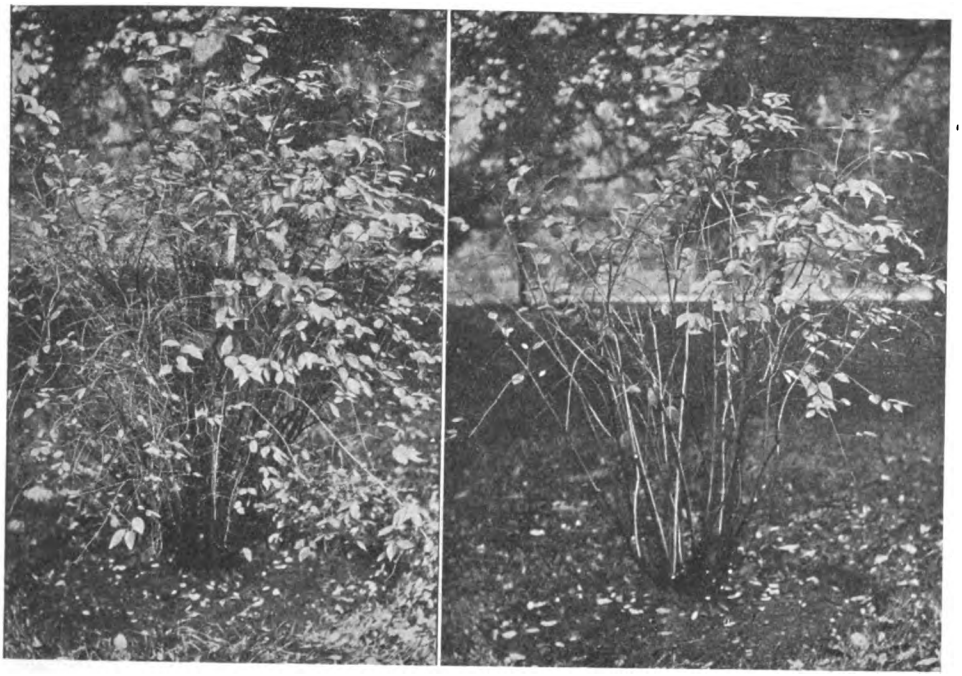
THINNING.

A fair proportion of necessary pruning —the word thinning more correctly describes the work—is, for various reasons, carried out in autumn and early winter. The diervillas and philadelphuses are really better dealt with immediately after flowering, but stress of work in other directions may delay it. I am not sure that this is a disadvantage, as when the leaves fall it is easier to see which wood can be best removed.

Since the main object of pruning and thinning is to maintain healthy and shapely bushes, the work done should tend in the direction of obtaining vigorous clean growth. Begin by removing the old flowering wood, either right to the base if the stems are crowded, or prune back to healthy shoots on the stems. Next, remove the very thin weakly twigs, and finish, if required, by shortening a little, any extra long vigorous growths tending to destroy the balance and shape of the bushes.

The ornamental fruiting bushes which require attention forthwith do not form a lengthy list, but it contains several very important families of plants. Bushes

Digitized by Google



A PHILADELPHUS BEFORE AND AFTER THE REMOVAL OF THE OLD WOOD.

of the common barberry, Berberis vulgaris, B. polyantha and the new hybrids, so beautiful in fruit, can be much improved by a judicious thinning of the stems to encourage the development of vigorous, healthy growths. The rose species soon become a tangled mass if neglected for a few years. To prune them back hard as we do the bedding roses in spring would mean the removal of most of the flowering wood, while to prune immediately after flowering results in the loss of the showy fruits in autumn. These difficulties are overcome by the periodical thinning or pruning, not necessarily every year, of the plants, giving us shapely bushes, with finer flowers and fruits.

Among the cotoneasters we have some extremely ornamental shrubs, a fair number being very showy in fruit and foliage. Here, again, careful thinning and regulating of the growths usually lends a more graceful appearance to the bushes and improves the fruiting propensities.

After fruiting, the old stems of the following brambles should be carefully removed to display the beautiful colouring of the stems and the distinctive characters of the thorns or prickles: Rubus biflorus and var. quinqueflorus, R. Giraldianus, R. thibetanus and R. lasiostylus.

I can call to mind no plant which responds more readily to the care and attention of the good gardener than Symphoricarpus racemosus, the common snowberry. It is perhaps worth mentioning here that botanists regard it as var. lævigatus, as the typical wild type is quite a dwarf shrub, 3ft. or less in height. At Aldenham, by deep cultivation, liberal manuring and systematic thinning of the bushes, the beauty and handsome appearance of this shrub can be seen to advantage.

A few shrubs, both deciduous and evergreen, if they require pruning at all, only need it to maintain their shapely appearance, or to prevent overcrowding. In this category may be placed magnolias, which I should place first on the list of plants "the less pruned the better."

From the foregoing remarks it will be gathered that the season and the method of pruning varies with the habit and nature of the bushes. As distinct from this, however, there is no better time of the year than autumn for a liberal "thinning" among hardy shrubs. A. O.

NOTES OF THE WEEK

AN ABNORMAL SEEDLING PLANT OF MEDICAGO SATIVA.

I ENCLOSE a photograph illustrating the strange appearance assumed by a seedling plant of Lucerne (Medicago sativa). The plant on the left of the photograph is a normal one, at the fourth week after germination. It will be noted that the course taken is as follows; after the cotyledons, a single almost circular leaf appears, after which there is a succession of trifid leaves, each leaflet being oval with a typical extension at the distal end of each mid-rib. The first leaf in the case of the "freak" plant formed an inverted cone (slightly compressed in obtaining the photograph); in place of the first trifid leaf appeared a single misshapen cotyledon-like structure on a petiole, followed by a similar distally indented one at the end of a third petiole. After this the plant seemed to be asserting its normal habit, although the next portion of the foliage was unable to complete its three leaflets. The appearance of the unfolded leaflets suggests that the future history of the foliage would have been normal. Both plants are of the same age, although four petioles have been produced from the stalk of the abnormal plant.—P. H. H. GRAY.

[This is probably another case of a plant showing variation in its juvenile form before it assumes the adult habit. There are many plants which exhibit a variation in this transitional phase of their life history and it is difficult to say whether such abnormality indicates a reversion to an ancestral type or not.—ED.]

THE KANSAS GAY FEATHER.

THERE are comparatively few gardens in which the gay-feathers or snake-roots, liatrises or lacinarias, are included, yet they are plants of effective appearance, although there are some who consider their purple colouring a little too intense. But they are valuable among other hardy plants and almost every one is struck by their handsome feathery-looking spikes of flowers, especially in a large plant with a number of spikes. I saw a large vase of the fine Liatris spicata exhibited in a first prize stand of hardy flowers the other day and the spikes doubtless helped to gain the premier award for the exhibit. They were excellent, although the flowers, which begin at the base, as in the case with most, were not expanded at the top, as they might have been had treatment such as is frequently bestowed upon gladioli for exhibition been afforded them. I have known a good many fail of success with these liatrises, and it is sometimes difficult to diagnose the cause of the losses. Even in a light soil, the natural medium for these flowers, they occasionally fail. I consider L. spicata and L. pycnostachya to be the best of these gay-feathers, and L. spicata to be the finer of the two. A good border of light, well drained soil appears to be the best for them, and, when once properly established they should succeed for a number of years without disturbance. Planting is best performed in spring, and propagation is effected by division of large plants. Some authorities prefer the name of lacinaria to that of liatris, but the former appears to have the priority by about thirty years. There are one of two dwarf forms of L. spicata. —S. ARNOTT.

AN ABNORMAL SEEDLING OF LUCERNE.

TWO FINE AUTUMN-FLOWERING BULBOUS PLANTS.

THE two referred to are Amaryllis Belladonna, the belladonna lily, and Schizostylis coccinea, the Caffre lily or crimson flag. During the last week or two when on visits to neighbouring gardens I have seen some very fine borders of A. Belladonna, while at Kew there is usually a remarkably good show close to the main entrance. This is a splendid species and somewhat variable in the colour of its flowers. A typical form

Digitized by Google

is a delicate pale rose shading to white at the centre, and there are also named varieties such as pallida, a pale form; rosea maxima, deep rose, which blooms a week or two in advance of the type; and purpurea, a rich purplish rose with a striking white centre. All flower about September, and the spikes appear in advance of the leaves. This plant requires a warm, dry and well drained position, and an ideal spot will be found in front of a range of greenhouses, also at the base of south or south-west walls. The rooting medium consists of loam, leaf-mould and sand, and now is a suitable time to select a plot and prepare the ground. The best time to plant is when the bulbs are dormant, and they should be planted 6ins. or 8ins. deep, surrounded with sand and left undisturbed for a number of years. When established they will flower freely. During their growing season, if the weather is dry, a thorough soaking of water will be beneficial.

Schizostylis coccinea produces its spikes of showy globular crimson-scarlet flowers during October and November, and if afforded a sheltered position on the rock garden or in a shrubbery border it presents a beautiful sight, while the spikes are most useful for cutting. It grows about 18ins. high and is a most valuable hardy plant from South Africa. The variety Mrs. Hegarty is similar to S. coccinea except that the flowers are a beautiful satiny rose pink in colour. It is a novelty worthy of a wide cultivation.

A suitable compost is sandy loam, leaf-soil and a liberal sprinkling of sand. This plant is a good grower and in a few years will become congested, when it fails to bloom freely. When this happens division of the roots will be necessary, and such work is best carried out in the spring. They should be planted in clumps of four or five shoots, about 9ins. apart. Apply plenty of moisture during the period of the plants' activity.—T. W. B.

ANEMONE APENNINA IN THE MASS IN WOODLAND SHADE.

ANEMONE APENNINA.

THIS Italian windflower is one of the easiest of anemone species to grow, and few are more effective in the spring garden. The narrow lavender-blue sepals are numerous, and with the central boss of cream-coloured anthers form a daisy-like flower, quite distinct from the star-shaped A. nemorosa, or wood anemone. Although always beautiful, even when waning, it is the newly opened blooms which are of the most brilliant blue, and a colony of this plant is never seen to such advantage as when the flowers are wide open and turned towards the sun.

One plant alone forms a charming little specimen with its divided leaves and numerous flowers; but it is when planted in extended colonies stretching away under trees that this windflower is seen at its best. In spring borders, it forms a fine contrast to the cream-coloured daffodils, such as Mme. de Graaff, St. Olaf, White Lady or Duchess of Westminster. It can also be planted to hide bare ground under Magnolia stellata, Forsthyia spectabilis and other early-flowering shrubs, as the anemones complete their growth before the shade above becomes too dense. The plant is of the easiest culture, and prefers light rather than heavy loams. It succeeds in all, however, if leaf-mould, sand or wood ashes be added to soils inclined to be heavy. The black, curiously shaped tubers are inexpensive, and should be planted in September or October. Given favourable conditions, they increase rapidly, and can be replanted with advantage every third year. A top-dressing of leaf-mould or decayed manure passed through a coarse sieve can be given in January with beneficial results. There is a white variety, but it is not so effective as the blue.—J. COMBER, *Nymans*.

TELEMLY SWEET PEAS.

SOME years ago I received a mixed packet of Telemly sweet pea seeds on the last day of November. On the following day, December 1st, the seeds were sown in six 4in. pots, four seeds being placed in each pot. Out of twenty-four seeds sown only one failed to germinate, and it is rather interesting to note that twenty-two seeds had germinated on December 14th, and some time later one more green tip appeared above the soil. On January 19th of the next year the plants were transferred to 7in. pots, potting on the four sweet peas as one plant, and staked. The late seedling was then only ½in. high, while one was 7ins. in height and the others were 6ins. The plants were carefully treated and shifted to the best positions as they grew apace, until eventually they were set in the conservatory. The first flower, a beautiful pale pink—a variety called Melody—opened on April 5th. The plants on that date were 3½ft. high. A pure white and a lavender variety each bore large and handsome flowers with good long stems. A crimson variety which was the last to come into bloom—six days later than Melody—was not so robust as the others; it did not grow so tall, while the flower stems were shorter and more slender, and only carried one bloom per stem. It may be worth while repeating what the Editor of THE GARDEN said in 1909 about the winter-flowering sweet peas. "Sweet peas have become amazingly popular of recent years and it is a flower that one never tires of; its freshness of colour and sweet scent are as welcome as those of the rose itself. To have sweet peas at Christmas is to bring the summer garden into the winter itself."—D. A.

THE DUTCH MYRTLE.

AN attractive little shrub well worth growing is the Dutch myrtle or sweet gale (Myrica Gale). The species is, of course, a native of Britain, and it is extremely common in the Lake District and also on boggy tracts in the south-western counties. The Dutch myrtle forms a little bush 2ft. or 3ft. high bearing neat leaves with toothed margins. These are of bright green colour and, more important still, they are most delightfully fragrant. In the old days the foliage was used in the hanging closets in order to keep moths away. The leaves of the Dutch myrtle remain on the plant until late in the autumn, and it is not very long after the fall that the catkins start to develop. These are in their full beauty quite early in the year, and they are by no means the least attractive feature of the shrub. In colour the catkins are of a very bright golden brown, which gives the little bush a most distinctive appearance. Although the Dutch myrtle is a bog species, it thrives in any moderately heavy soil. The fact that the ground is rather poor is an advantage, for then the bushes are much more compact in their growth and the leaves are usually more aromatic. The Dutch myrtle is a useful subject for the borders of the shrubberies, and the writer has even seen it growing in moderately dense shade. Propagation is easy, for practically any portions of the underground shoots, with a little bit of stem attached, will grow.—S. LEONARD BASTIN, *Bournemouth*.

NATIVE LYSIMACHIAS IN CULTIVATION.

JUDGING from the nature of notes on British plants appearing in various horticultural papers from time to time, one is led to conclude, and I venture to say, rightly so, that the present day horticulturist evinces a strong desire to become better acquainted with his or her native flowers.

To pillage the haunts of our rarer plants is, indeed, a sin, but to include some of the more plentiful, yet useful of wild flowers in the garden is to increase one's own knowledge and to add interest to the garden in the eyes of visitors.

Some natural orders of British plants are so composed that practically every species contained therein is sufficiently attractive to be grown in cultivation—such an order is primulaceæ.

The genus to which I wish to draw attention is lysimachia, containing as it does dozens of species, of which four are native.

L. nemorum, usually referred to as the yellow pimpernel is one of the most plentiful of the natives. Seen in its wild state it asks for admiration, for its dainty yellow flowers, arising singly from the axils of the leaves seem to glisten like tiny lights among the rich green leaves. Its flowering period is throughout June and July, or, maybe, a little longer. It is of a semi-procumbent habit and

Digitized by Google

does best when given a shady spot along the bank of a pond.

L. Nummularia is known to all and sundry as Creeping Jenny, and though not so plentiful as L. nemorum, has nevertheless a wide distribution throughout the British Isles. Though in nature it seeks a fairly shady home, it is one of those very obliging plants which can be relied upon to do well wherever planted. Obliging plant this Creeping Jenny! but, to some, alas, a weed.

L. thyrsiflora, the Tufted Loosestrife, is the rarest of native lysimachias, and is restricted to a few places in the north of England and over the border. By reason of its lance-shaped leaves it is readily known from its kindred and is also characterised by the small yellow flowers which are borne thickly on a stem arising from the axil of a leaf. In cultivation it seems to enjoy a shady spot in a swampy part of the bog-garden.

L. vulgaris the yellow loosestrife, may be regarded as the tallest growing native lysimachia and is very commonly found along the river banks, particularly in the south of England. Though it enjoys best a shady place, it will, if required, adapt itself to the drier conditions of a garden and can be used with commendable results in the herbaceous border.—W. H., *Glasgow*.

SHRUBS IN ARGYLLSHIRE.

WHILE on a recent visit to Benmore, Mr. Harry Younger's estate in Argyllshire, which, as many of your readers are probably aware, has been gifted to the nation for forestry purposes, I was struck by the number and variety of shrubs which were doing so well in the shrub garden; and in view of the recent correspondence on shrubs in the West of Scotland, I thought readers of THE GARDEN might be interested to hear of a few.

One of the most interesting occupants is a fine specimen of Drimys Winteri, the Winter's Bark, which, from its appearance, is thoroughly satisfied with the west coast climate. At present it is about 5ft. high and gives every indication of becoming a sturdy shrub. The young, smooth shoots, tinged with bright red, and its bright pale green aromatic leaves, give a striking and handsome appearance to the shrub. In close proximity there is a good specimen of a conifer which is rarely seen in gardens, Arthrotaxis laxifolia. This has reached a height of from 9ft. to 10ft., and is of good habit. Although a native of Tasmania, it apparently finds the heavy moisture and mild conditions of Argyll congenial. Another interesting conifer to be seen is Fitzroya patagonica, a native of Chile, which is also thriving well and gives every promise of equalling a specimen which Mr. Dallimore quotes in his book at Stonefield, Argyllshire. A fine bush of Cercidiphyllum japonicum attracted attention by its brilliant autumnal tints, while near by a fine bush of Hypericum Hookerianum was laden with its bright yellow blossoms. The stranvæsias, notably S. Davidiana, and the euonymus, were a picture, with their clusters of bright red fruits, shown off to advantage by the background of foliage. The coral plant, Berberidopsis corallina is also to be seen growing well on a south wall, in association with solanums and clematis. When in full flower this evergreen is of remarkable charm, and although as yet of small dimensions, its beauty could be appreciated. Desfontainea spinosa grows exceedingly well and there are numerous specimens of 6ft. to 7ft. high and about 5ft. through. Another interesting plant which is rarely found outside and whose presence further testifies to the mildness of the west coast, is Myrica asplenifolia. Although it might not be termed a handsome shrub, yet it has a charm of its own. There are many other interesting shrubs, too numerous to mention. Pernettya grows everywhere, in association with Rhododendrons ponticum and campanulatum. One or two fine palms can also be seen in woodland shade and do extremely well. As for conifers, the number of species growing in that district is legion and each seems to try its hardest to outstrip its neighbour. It certainly would seem to be the ideal spot for all our exotic species, of which we have so many nowadays.

No doubt, the great success which has attended the cultivation of all shrubs in this area of Scotland is due to the heavy precipitation of moisture throughout the summer months, and to the absence of really hard frosts in the winter months. In addition, full advantage can be taken of the shelter of the hills to prevent undue exposure to the cold, north winds.

Although the foregoing is a somewhat meagre description of an interesting collection, it will serve to show that we need not be pessimistic about gardening on the west coast of Scotland. As your correspondent, Mr. Austin Mackenzie, says, many of the Argyllshire gardens contain plants of more than passing interest, and Benmore is one of these. It is indeed fitting that the gift of Benmore will, in all probability, lead to the establishment of a national botanic garden in this fine situation, where already there is a large number of interesting trees, shrubs and plants of botanical as well as of horticultural interest.—G. C. T.

THE WINTER'S BARK, DRIMYS WINTERI.

MYRICA ASPLENIFOLIA IN THE OPEN.

THE OLD DOUBLE LILAC PRIMROSE.

SOME of the double primroses are not only difficult to procure but are notoriously troublesome to keep without special care. One of the best, a good doer and free flowerer, is the old double lilac variety of the common primrose, P. acaulis. It frequently flourishes where all others have failed. But those who have experienced trouble with this and other double varieties should give them a good deep loam, a partially shaded position, plenty of water in dry weather in spring and summer, and should also take off some of the first flowers as soon as they decay. Some advise covering with a sheet of glass in winter to throw off excessive wet, but this old double lilac form does not appear to call for this. Plants should not be allowed to grow too large without division, which should be performed as soon as the flowers are over.—S. A.

FOR DEEP SHADE.

IN situations deeply shaded by trees, it is not many plants that will succeed. Those who have tried the various shrubs commonly recommended without good results will find a solution of the difficulty by planting the butcher's broom (Ruscus aculeatus). This plant, which is a hardy evergreen of exceptionally neat growth, will flourish where practically nothing else will grow. Butcher's broom thrives in the dense and unchanging shade cast even by such trees as hollies, yews and evergreen oaks. The large red berries, almost the size of cherries, which the ruscus produces are extremely handsome. To obtain these it should be borne in mind that the sexes are on different plants, and, on this account, male and female specimens must be secured and planted in close proximity. The butcher's broom is not at all particular as regards soil, and seems to be able to withstand great dryness and somewhat moist conditions equally well. Of course, Ruscus aculeatus is a native species, and, although rarely abundant, has an extremely wide distribution, at any rate, in England.—S. L. BASTIN.

A FINE YOUNG SPECIMEN OF ARTHROTAXIS LAXIFOLIA.

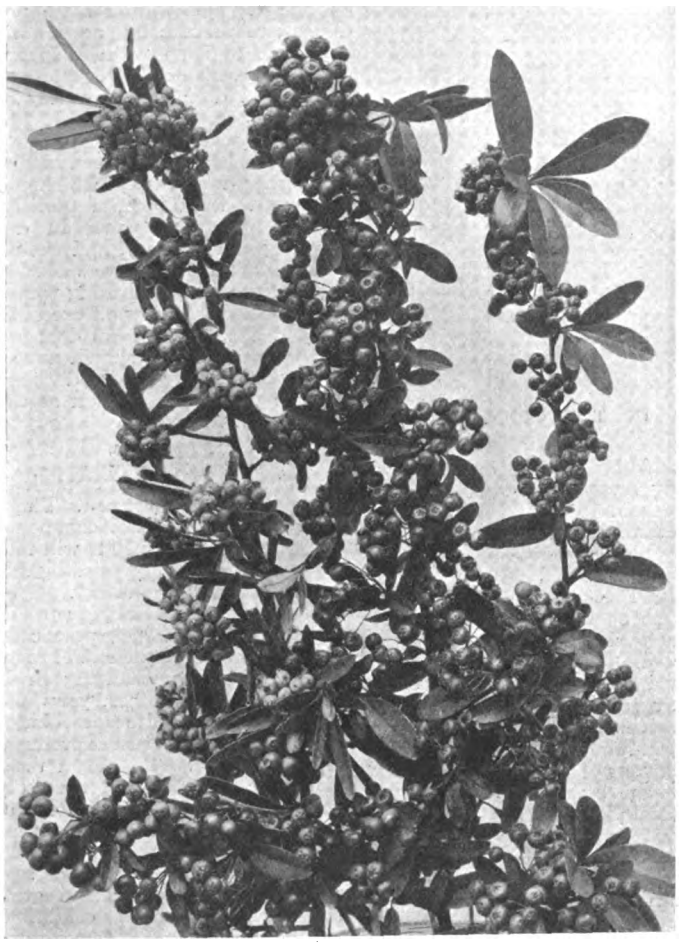
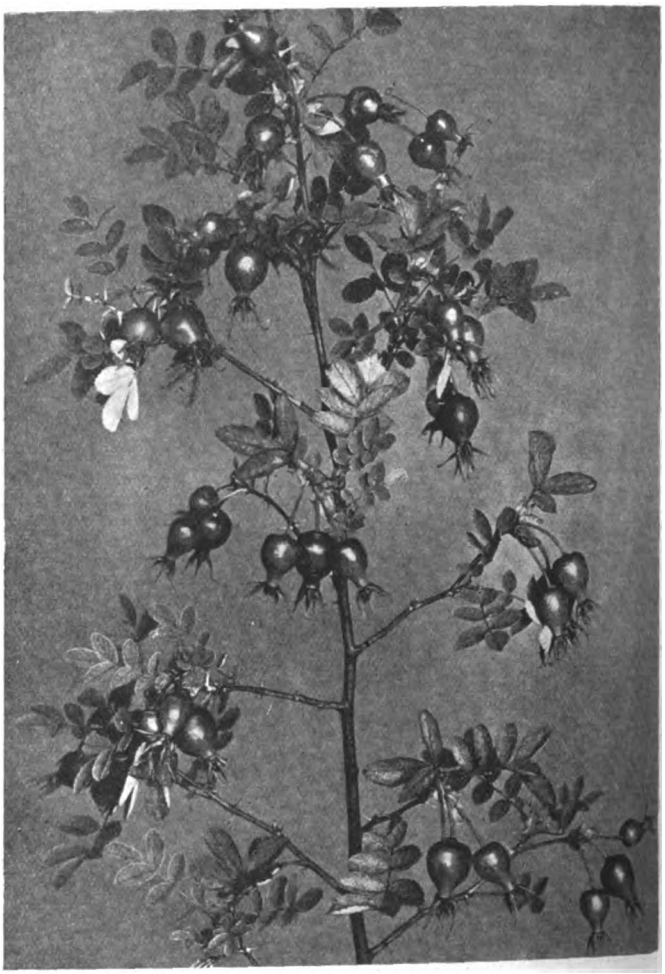
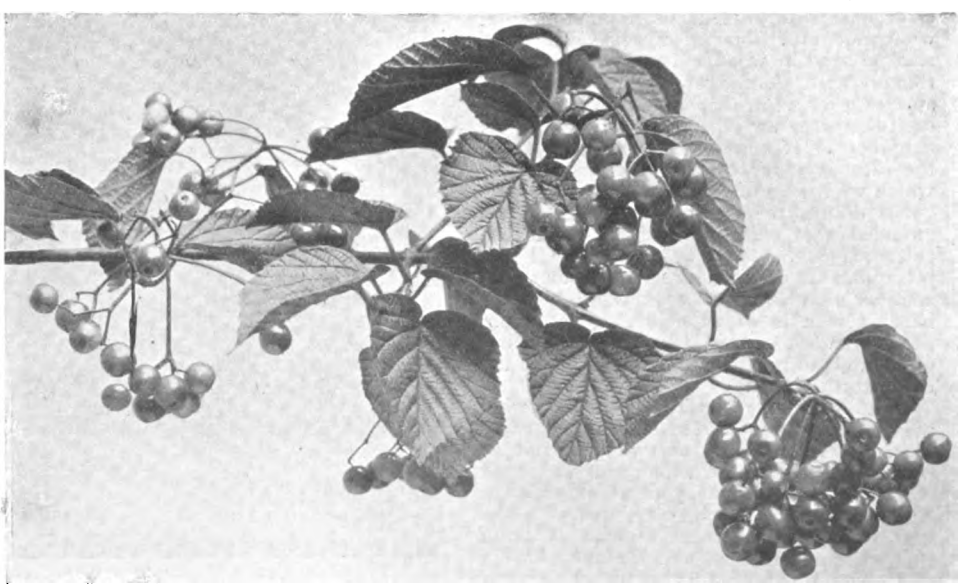
ALL GARDENS ARE MADE MORE BRILLIANT



The orange-red berries of Pyracantha coccinea Lalandei. This popular plant is typical of this free-fruiting genus, which is so often seen growing against a wall.



The majority of rose species possess beautiful fruits, and in some cases the plants are as handsome in the autumn as they are in flower during the summer. Our illustration shows the deep red hips of Rosa sertata.



Many of the fertile viburnums bear handsome fruits, among them the common guelder rose, V. Opulus. Our illustration shows one of the many Asiatic viburnums whose fruits are a distinct acquisition. Viburnum lobophyllum has handsome white flowers and shiny blood-scarlet fruits.

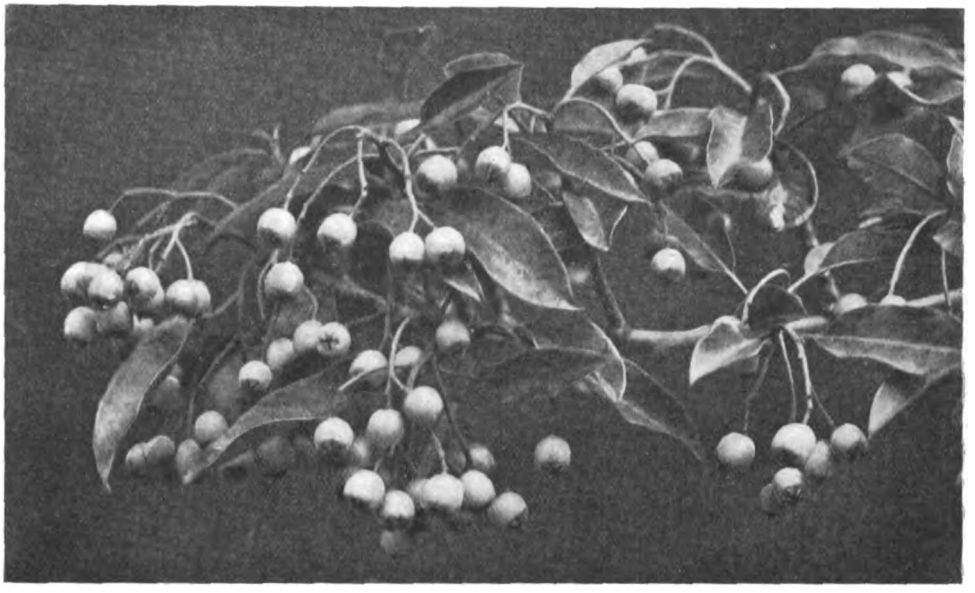
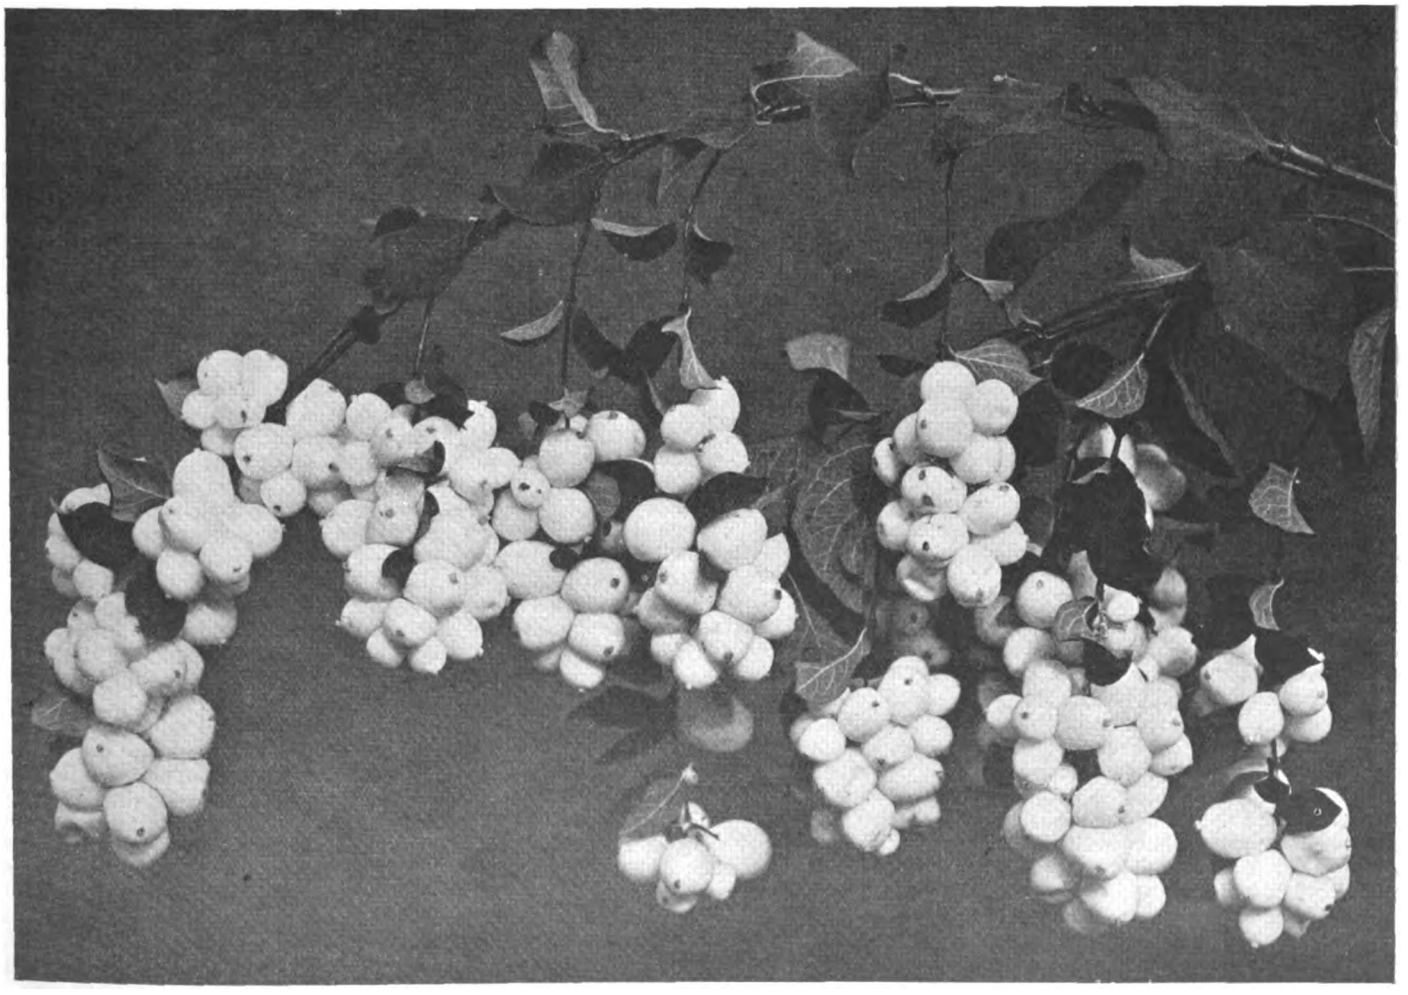
IN AUTUMN BY BERRIED TREES & SHRUBS

Another brilliant red berrier of late autumn, Stranvæsia undulata, is a native of China, where it grows to considerable size. The stranvæsias are an evergreen genus, close relatives of the photinias. They are all noted for their free fruiting qualities.





A handsome well fruited spray of Symphoricarpus occidentalis, commonly called the wolfberry, a close ally of the well known snowberry. This genus includes a few of our most ornamental shrubs for the garden, their chief attraction being the large clusters of beautiful white fruits which are retained well on into the winter.

Digitized by Google

THE TALLER-GROWING HARDY HEATHS

FEW families of hardy flowering shrubs provide the gardener, and to a considerable extent the landscape architect, with such a wealth of material for mass planting and grouping in the pleasure grounds and open woodland as the heaths. Many large estates make a feature of a heath garden. In this, as a rule, the dwarf heaths predominate, but when free use is made of the subjects of these notes, they provide the planter with very much wider possibilities in securing distinct features and charm by effective grouping and massing. To mention only one valuable asset, a representative collection of hardy heaths provides a succession of flowers throughout the year.

ERICA AUSTRALIS, VAR. MR. ROBERT.

Most of the heaths do not thrive in soils containing any appreciable quantity of lime, exceptions being carnea, darleyensis and stricta. As is very well known, heaths predominate on peat land, but in gardens they do equally well on sandy, loamy soils if leaf-mould and peat are added when planting.

Autumn is the best season for planting heaths: when the soil is still warm, and the weather as a rule mild and favourable for the work. It is most important to transplant heaths with good balls of soil attached to the roots.

In addition to their own beauty in the garden and pleasure grounds, these taller heaths are very useful to provide protection and shelter for newly planted choice and rare shrubs, such, for example, as Eucryphias pinnatifolia and cordifolia Stuartias, styrax, magnolias, Disanthus cercidifolia, Hamamelis mollis and Viburnums fragrans and Carlesii.

E. ARBOREA.—Among the larger growing heaths this species is the tallest, attaining, in the milder parts of the country, the dimensions of a bushy tree up to 20ft. in height, with a distinct trunk. Hence the popular name of the "Tree Heath" is used. It is a native of southern Europe, north Africa and the Caucasus, and is said to have been first introduced to British gardens in 1658.

The white blossoms with a sweet, honey-like perfume, are very freely produced during the early months of the year, being at their best in March and April.

Its nearest ally is E. lusitanica (syn. codonoides), which is distinguished by a more shrubby plumose habit, longer, purer white flowers, and a lengthy season of blooming—from late autumn to spring. With a pocket lens it is easy to pick out E. arborea, because the hairs on the young shoots are branched.

The variety alpina is a native of the mountains of Cuenca, Spain, growing at about 4,500 ft. elevation. Compared with E. arborea it has stiffer and more upright growths, the leaves are a brighter green, and the flowering season is later. It is hardier than E. arborea, and is more attractive throughout the year, because of its rich vivid green foliage. First introduced to Kew in 1899, the tallest plants are now 7ft. to 9ft. high. The tiny bell-shaped white blossoms are very freely produced in some seasons, but without these it is worth growing for the rich green of the foliage in winter.

E. AUSTRALIS.—This is one of the most beautiful of all the heaths cultivated outside in our gardens. The flowers are bright rich rosy-red, freely produced during April and May. It is the least hardy of the heaths to which attention is drawn in these notes. We have not, however, experienced a really severe winter since that of 1894-95, when many plants were killed outright, though on several occasions, notably in 1904-5 the ends of the shoots were killed.

In habit the plants are more spreading than most tall heaths and vary from 4ft. to 6ft. high, sometimes more in the sheltered gardens of the south and west. The rich rosy-red flowers are borne in clusters at the end of the shoots, lasting for at least a couple of months.

E. australis is a native of Spain and Portugal, and is sometimes known as the Spanish heath. It has been cultivated on and off in British gardens since 1769.

As recently as 1912 the late Lieutenant Robert Williams, a son of Mr. J. C. Williams of Caerhays Castle, Cornwall, collected a white form of E. australis on the mountains of southern Spain, near Algeciras. Lieutenant Williams did not live to see his very valuable find flourishing in British gardens. He was killed in the Great War during the hard fighting near Loos in October, 1915, and it is fitting his memory and love for plants should be linked with this charming white-flowered heath, which Mr. Bean named variety Mr. Robert. As indicated by the illustration it is a typical E. australis in habit with attractive clusters of white blossoms. A most charming heath and worthy of being planted in large quantities in the pleasure grounds and open woodland.

E. LUSITANICA.—This is the most popular of all the taller-growing heaths in the gardens of the south and west, where it is a splendid winter-flowering shrub. In mild localities the plants commence flowering in October and continue right through the winter until April. In Dorsetshire and Cornwall large quantities are grown to supply cut sprays for market. As it lasts well when cut, there is very considerable market for such a charmingly fragrant, white-flowered shrub, not only in Covent Garden, but in the Midlands and Scotland.

At Lytchett Heath, near Poole, self-sown seedlings have spread over several acres of ground, the tallest plants being from 10ft. to 15ft. in height.

Though in the London district we place E. lusitanica in the list of plants liable to damage when we get degrees of frost near the twenties, it has withstood 18° and 19° of frost in Hampshire and Dorsetshire.

As the name indicates, E. lusitanica is a native of Portugal, and it also grows wild in Spain. Many nurseries use Lindley's name of E. codonoides for this heath, which, for profusion of flowering is unsurpassed by any other erica.

E. MEDITERRANEA.—This is more bushy in habit than the preceding species, forming close, shrubby specimens 5ft. to 7ft. or more in height. At Kew this heath has been extensively planted in large masses, giving a beautiful effect in spring and pervading the air with a delicious fragrance when covered with rosy-red flowers. The flowering season extends from March to May.

In typical E. mediterranea the flowers are rosy-red, the best form, grown in nurseries as var. superba has richer red flowers, suggesting the colour of E. australis. This is obviously the variety to propagate and plant freely. The white variety alba is a charming plant, not so

Digitized by Google

robust in habit, but a very showy heath; var. hibernica, or glauca, is an Irish variety with bluish foliage of rounded habit, not so tall as the type. E. mediterranea is a native of Spain, western France and Galway and Mayo, Ireland.

E. SCOPARIA.—This is a native of central and western France, where, because of its use for broom-making, it is known as the Besom heath. As a garden shrub it is interesting and useful for shelter and shrubberies, but of no decorative floral value. The branches are of upward habit, 8ft. to 10ft. high. The greenish blossoms are very freely produced in May and June, but are not showy.

E. STRICTA.—This is a summer-flowering heath, and for that reason is worthy of much more attention from cultivators. The rosy blossoms are freely produced from June to September, the plants ranging from 3ft. to 6ft. or 7ft., sometimes more in height. It is hardy at Kew, though a native of southern Europe, Italy, Sardinia, Corsica and southern Spain.

E. VEITCHII.—This beautiful heath originated in the nurseries of Messrs. R. Veitch and Sons at Exeter. The plant is presumed to be a hybrid between E. lusitanica and E. arborea, as it possesses characters of both species. This chance hybridising was no doubt due to the work of bees, as both plants were, and are still grown in large quantities at Exeter.

Those familiar with the beauty of E. lusitanica in Dorsetshire and Cornwall, may have their doubts as to the hybrid flowering more freely than this parent. We think it does at Kew. In a bud state there is a pink tint in the flowers which gives place to a snowy whiteness. In mild weather the first blossoms open early in the year and provide a succession of fragrant blossoms until April. E. Veitchii is certainly one of the best hardy heaths and most effective for massing in the pleasure grounds and shrubbery borders. KEW.

THE BREAKING OF TULIPS

(*Continued from page* 600.)

IN 1863, out of 750 breeders planted by Storer—the raiser of "Dr. Hardy" and "Sam Barlow"—not more than fifty remained breeder. Similar results occurred with other growers: with Dr. Hardy himself at Warrington especially, and Dr. Horner, his protagonist in learned and scientific discussions on the merits of the flower. It must be remembered in this connection that every florist kept a record of the doings of each bulb and its progeny, and by the aid of his book could identify the bulb in book, bed and cabinet; the fifth in the fourth row, the sixth in the seventy-second row, and so on; a fresh book would be made at planting time, and the old records treasured and kept for reference.

In 1860 J. F. Wood, who had taken his bulbs to South Australia, noticed their tendency to "run to breeder," and grow so excessively luxuriant that they were out of character, he concluded they must be planted in poorer sandy soil. One has heard the expression "starve them into refinement"—of marking—used in days that are gone.

In 1863 Parkinson visited Hepworth and recorded "a phenomenon never seen before": of a bed of 33yds., planted with rectified tulips, containing about 1,400 bulbs, about one third of them had gone back to breeder, especially mentioning "Everard" and "George Hayward." "Everard" had not been known as a breeder before. "President" which he had shown in his twelve stand of rectified blooms the previous year, had now gone back to breeder. Authentic cases of going back are rare.

In raising tulips we find that seedlings are more vigorous and prolific in the first ten years of their growth than in the second ten years; but are not all plants more vigorous in their earlier years than in the later years of their existence? Do they not go off with a rush in youth and "sober down" afterwards?

Investigation into the diseases of potatoes has established several forms of "mosaic," and it has been shown that these diseases are transmitted from plant to plant by the action of sucking insects—aphides. Some American scientists ascribe the "breaking" of tulips to the "mosaic" disease; it is stated "all the classes of bulbs, hyacinths, narcissi and tulips, are more or less affected with mosaic disease."

It has been noted that tobacco plants have somewhat similar variegation in foliage and in bloom to that which characterises the tulip in the broken condition. In the ornamental tobaccos the similarity of mosaic and the breaking of tulips is said to be striking, but the disease aspect of breaking in tulips has not yet been definitely investigated. Experiments in artificial breaking of tulips have, so far, given results that are largely negative; it is claimed that breaking in other plants is caused by mosaic. The aphis is suggested as the main carrier of disease.

We are told that at Billingham, Washington, Dr. Griffiths has not had broken Darwins; fortunately, aphides have never been numerous there in the bulb fields of the U.S. Department of Agriculture, which are under his direction.

Last year, at lifting time, breeder bulbs were carefully stored in small bags, each bulb in a separate bag, and kept free from insect visitation; in the following blooming season about the same proportion of broken blooms were thrown by these wrapped up bulbs as by bulbs stored without the special envelope. On general principles one would desire to prevent the numerous visits of aphides, were it an easy matter, but to keep plants from visitations of insects requires more paraphernalia than an ordinary layman possesses, so no attempt was made to protect the growing plants even though the aphides "come in clouds."

THE TYPE AND ITS BREAK.

Some bulbs of broken varieties were, as an experiment, dressed with sulphur a month or two before planting, to see if a reversion to the breeder stage could be induced, but only negative results ensued in the following blooming time.

Many of our trade growers are perturbed by the numerous breaks they find in the Darwins and in the cottage varieties. They desire to keep to the self-coloured form and to discourage, if not entirely prevent, breaking.

Digitized by Google

In earlier years the florists were concerned with the break and how to induce it; in these later years lovers of the tulip are concerned with the break and how to prevent it. The problem is the same, though the end to be desired differs. The old florists desired broken blooms, the well marked flowers; the multitude now prefer the self-coloured forms, and would keep their flowers in that breeder stage.

Maund, long ago, said the break is an abnormal state and suggested that the flower, when perfected in the estimation of the florist, is the production of an enfeebled plant, the result of old age.

In the absence of scientific evidence as the result of well ordered research, the idea prevails that breaking is a natural result, even though we know tulip plants and bulbs may be subjects of infection by visitations of sucking insects, and there are many phenomena that might lend countenance to the suggestion that disease is the cause of "break."

Hale. C. W. NEEDHAM.

CORRESPONDENCE

EUCRYPHIA PINNATIFOLIA IN WEST OF SCOTLAND.

SIR,—Readers of THE GARDEN may be interested in the enclosed photograph of a Eucryphia pinnatifolia in full bloom, 30ft. in height, growing in Sir Ian Malcolm's garden here. The shrub is a native of Chili and rather rare in this country, where it seldom, if ever, attains this height. The shrub in question is thirty years of age.—LADY MALCOLM, *Kilmartin, Argyll.*

A HANDSOME BUSH OF EUCRYPHIA PINNATIFOLIA.

GARDEN RUBBISH.

SIR,—With reference to Mr. Macself's article under the above heading in the issue of THE GARDEN for October 3rd, page 561, there are many points upon which I beg leave to disagree.

With regard to the use of farmyard manure, very little need be said. The results of its use for centuries have been generally so satisfactory that it will take more than the fact that such manure may carry infection to shake the faith of the average enthusiast in the use of this material in the form in which it is received.

Mr. Macself may wish to suggest that a certificate should be obtained from the vendor that all animals assisting in the production of the manure had been fed wholly on microscopically pure materials, but while waiting for this it is at least conceivable that some rash gardener will be found ready to take the risk of the pestilence and try the filth without a certificate.

Regarding the manurial value of garden refuse, however, the average gardener needs to be told that its chemical constituents are superior, weight for weight, to farmyard manure, because some of the vital constituents have been drawn from the latter in the process of giving nutrition to the animal.

He should also be told that, apart from the total destruction of humus, the incineration of such refuse results in the loss of all the nitrogen and most of the phosphates, while the potash remains in such a soluble form that it soon disappears unless preserved perfectly dry and applied to growing crops (which it never is). Under ordinary conditions, therefore, the value of the residue from incineration is almost negligible.

While many gardeners will be disposed to admit the value of properly decomposed garden refuse, they will be deterred from giving it a fair trial if they believe in the statements made that it will cause an increase in garden pests and diseases. Many a gardener will rather face a certain impoverishment of his soil than run the risk of infected soil and crops. Added to this many gardeners need very little encouragement in the use of the bonfire. In the opinion of many it is a much tidier and less laborious way of disposing of rubbish.

I have no desire to minimise the undesirable effects of plant pests and diseases. My contention is that the danger from this source is not lessened by the incineration methods advocated by Mr. Macself, neither is it more convenient if a properly controlled method of decomposition is followed.

I am convinced that the incinerator as a controller of pests and diseases is impracticable. Of what use is it to try to control potato blight by burning the haulm blackened by Phytophthora infestans when the damage is done and the soil and probably much of the surrounding vegetation are already infested? I had imagined that this disease can only be controlled by attacking it at an earlier period of its life-history.

Recent research in bacteriology indicates that in most cases more importance must be attached to the conditions governing development of a disease than to the mere presence of a disease germ. In many cases the distribution of disease germs is general, and only favourable conditions are needed for the germ both to multiply and to propagate the disease. A healthy well nourished subject is the governing factor in combating disease, and under these circumstances it is of little use to destroy a few germs or spores unless all the gardens in the neighbourhood are sterilised. Mr. Macself would carefully burn up all the diseased stems and leaves that can be collected, but he conveniently ignores the myriads of bacteria on the ground and on the stems and leaves of permanent plants. Further, in respect of these colonies of disease which he has succeeded in bringing to the furnace, he does not enlighten us as to the method of chaining them to the stake.

I contend that the controlled method of decomposition is likely to be more effective in destroying harmful germs and seeds than any method of incineration.

I have dealt with the theory of the subject at some length, but the merits of every question must in the end be judged by results. I am content to base my main challenge to Mr. Macself on the results obtained at Pyrford, where for many years the theory outlined above has been consistently and wholeheartedly practised, that is to say, the bonfire has been wholly barred and vegetable refuse of every description, including the filth and pestilence, has been subjected to controlled decomposition.

The result is that a waste of heath and scrub has been converted into a productive garden largely without the aid of farmyard manure, while the attacks of pests and diseases are normal and stationary.—W. AUTON, *Pyrford Court, Woking.*

[In this, one of the most controversial questions in the gardening world, it may be safely stated that organic matter is required for manurial purposes in all gardens, and whether one uses garden rubbish or farmyard manure, it is well-nigh impossible in practice to obtain it free from fungus spores or the eggs and larvæ of insects. Authorities are agreed that sterilisation is next to useless unless carried out on a huge scale, which is impossible owing to the rapidity of breeding of insects and the production of fungus spores which blow readily from place to place. In our opinion, it is unlikely that any garden will ever be free from pests of some description. It may be said that the heat of fermentation arising in a well made heap of vegetable refuse is generally adequate to destroy the majority of insect eggs and larvæ. The danger, however, appears to lie with fungus spores and cysts (whose distribution, it may be mentioned in passing, is almost ubiquitous), which remain uninjured in the process. Against

Digitized by Google

many no remedial measures can be taken. For example, potatoes infected with wart disease must be excluded from the rubbish heap and burned as soon as found, as with brassicas infected with finger and toe. It is a case in point where general rules cannot be laid down, and the gardener must use discretion in following a certain line of action.—ED.]

ORCHIDS AND OTHER FLOWERS AT WESTMINSTER

DESPITE the unfavourable weather of the previous few days there was a very fine display of autumn flowers at the fortnightly meeting of the Royal Horticultural Society, held at Vincent Square on October 20th and 21st last. The majority of the floral exhibits showed little or no damage by frost or wet. The roses were in fine condition and reflected great credit on all the firms who were showing.

The orchids, which were the special feature of the Show, again proved of considerable interest to all lovers of these aristocratic plants. Although no novelty was presented which was considered worthy of a first-class certificate, the general standard was well up to that seen in previous years, and four awards of merit were given.

The only gold medal was awarded to Messrs. J. and A. McBean, Cooksbridge, Sussex, for an extensive exhibit covering 240 sq. ft., and in which quality and style of arrangement were prominent features. But few orchids have obtained greater popularity than Cypripedium Maudiæ, a beautiful hybrid with light greenish-coloured flowers, and particularly adapted to amateurs' collections. This firm staged several well flowered examples.

The challenge cup offered by the orchid trade was won by Mr. H. T. Pitt, Stamford Hill, N., for the third time, and it has thus become his property. This amateur had several varieties of Cattleya Hardyana, a natural hybrid which has also been raised artificially, and in a form with albino sepals and petals. The other amateur who competed for the cup was Mr. J. J. Joicey, Witley, Surrey, who had an excellent group of modern hybrids, and for them received a silver-gilt Banksian medal. Sir Jeremiah Colman, Bt., Gatton Park, Surrey, also had an interesting group of Cattleya hybrids, mostly large specimens selected on account of the uncommon bluish and lilac tints of the flowers.

No fewer than five trade growers received silver-gilt Banksian medals for meritorious exhibits. Messrs. Sanders were particularly strong in the Burmese Vanda cœrulea, and in richly coloured varieties of Cattleya Fabia, which are always appreciated for autumn decoration. Messrs. Charlesworth and Co. filled the centre area of their group with fifty flowering plants of Dendrobium phalænopsis, imported from North Australia early last year, while on each side were examples of their recent novelties in odontonias, produced by crossing Miltonia vexillaria with various odontoglossums.

Messrs. Black and Flory had an exhibit in which yellow-flowering Cattleya hybrids predominated, and although progress in the making of a large flower of yellow colour is somewhat slow, there were many varieties which showed a marked improvement. At present, brightness of the yellow colour is generally associated with rather narrow segments. Messrs. Cowan and Co. specialise in cattleyas, and their several examples of Brasso-Lælio-Cattleya British Queen comprised some of the largest orchid flowers which have so far been produced. In Brasso-Cattleya Nora, of slightly smaller size, the flower is of a deeper tint of mauve.

Messrs. Stuart Low and Co. exhibited several rare species in their group, including a variety of Cattleya bicolor with a bluish lip, and the pretty Oncidium oblongatum citrinum. This firm had some excellent varieties of Lælio-Cattleya Profusion, which is now one of the most popular hybrids of recent origin.

In Messrs. Cypher and Sons' noteworthy exhibit of the popular cypripediums, a fine variety of Elatior stood out prominently, as also did Cypripedium Shogun, which originated in the Westonbirt collection. Mr. Harry Dixon staged a group containing several of the easily grown hybrids, and also some of the species which were popular in days gone by and are now again becoming so with the present generation of amateurs.

The condition of the rose exhibits was surprisingly good, considering that the season is so far advanced. Many of the blooms showed no sign whatever of any damage by wind or rain. Messrs. George Prince had a collection which was quite unblemished. Among them Lady Hillingdon, K. of K., Los Angeles, Lady Inchiquin, Frau Karl Druschki, Souvenir de C. Pernet, Lady Pirrie and Allan Chandler, a new perpetual-flowering semi-double pillar rose of vivid scarlet. Messrs. Chaplin Brothers staged some splendid roses. Perfect blooms of that lovely white single Innocence were shown, together with Henrietta, Mabel Morse, K. of K., W. F. Dreer, Emma Wright, Eric Holroyde and others. A most effective stand was that of Messrs. Dickson. The varieties chosen were few in number, but bold groups of those selected made the stand a blaze of colour. Shot Silk (with its fragrant shaded pink flowers) was the most prominent variety. Lovely blooms of K. of K., Betty Uprichard, W. F. Dreer, Scarlet Glory and Earl Haig were also included. Mr. J. Pemberton staged a varied collection, the best of which were Joanna Bridge, Golden Emblem, Isobel Ruth, I Zingari and Pax.

For about the first time this year exhibits of the beautiful and easily grown greenhouse bulbs, the nerines, were on show. A fine collection of new hybrids was shown by Messrs. Barr. Countess Bathurst was a beautiful blush-white variety with a rose centre; Flambeau, a fiery scarlet; Bodyguard, a crimson shot with purple—an attractive colour; Royal Prince, a handsome scarlet; and Peter Barr was a beautiful rose covered with a golden sheen. The truss of the latter variety was large and borne on a stiff stem of great length. Knight Templar, Firelight and Scintilla were also good varieties. An interesting group of N. Bowdeni was exhibited by the Duchess of Wellington (gardener, Mr. H. Beckenshaw). This species is one of the hardiest of the family, and the specimens shown on this stand were picked from an outside border at the base of a yew hedge, where the nerines bloom in great profusion. Nerines were also shown by Mr. W. H. Walters and a few by Mr. G. Reuthe. Mr. Walters is now in charge of Colesbourne Park Gardens, Cheltenham, the gardens of the late Mr. H. J. Elwes. Such varieties as Mrs. H. J. Elwes, the Hon. Miss Gibbs and Snowflake were shown by him.

Messrs. Sutton and Sons had an excellent exhibit of many members of the brassica family. The savoys and cabbages were particularly fine in size, and the outstanding varieties were Savoy Sutton's Dwarf Green Curled, Savoy Cabbage, Sutton's Selected Drumhead, Cabbage Sutton's Early Market. The Portugal cabbage, Couve Tronchuda, a most useful but seldom grown vegetable, was also seen on this stand. A good collection of vegetables grown without the addition of farmyard manure to the soil was shown by Viscount Elveden.

THE EXHIBIT OF ORCHIDS, STAGED BY MESSRS. CHARLESWORTH.

Mr. J. W. Forsyth staged an interesting exhibit of delphinium seedlings which were sown during October of last year. In spite of several degrees of frost during the second week of this month the blooms of these seedlings were uninjured.

Some good groups of chrysanthemums were also staged, and representative collections came from Messrs. Keith Luxford, Messrs. Godfrey and Son and Mr. W. Yandell. Messrs. Godfrey had some fine blooms of the varieties Godfrey Gem, Gold Cup, Monica and Jean Pattison. The two well known firms of Messrs. Allwood Brothers and C. Engelmann had large collections of newest carnation varieties. The other groups in the hall were chiefly of herbaceous plants, while a few individual exhibits, such as the gesnerias shown by Mrs. Howard Palmer, added greatly to the variety and interest of the show. Messrs. F. G. Wood made a sombre little pinetum of dwarf conifers: Picea

Digitized by Google

occidentalis pygmea, that looks like a fantastic green rock; Pinus Remontii, a forest tree in miniature; Cupressus Fletcheri nana, in tarnished silver; and Thuya "Rheingold," in dull gold. Against this background the pale, late blooming variety, Aitchisonii, of Crocus speciosus shone out, delicately alive and beautiful. Another fine autumn crocus, C. medius, was shown by Messrs. Reuthe; this easily grown rarity from the Riviera is distinct from nearly all other crocuses in its peculiar tone of purple, and from all in the star of deeper colour at the base of the cup. Every autumn, one wonders why the wild crocuses are so seldom seen in gardens.

Among other exhibits were the following:

Fruit.—Messrs. Buckwell and Lockyer and Co., J. J. Kettle, Laxton Brothers and G. Trinder.

Hardy Plants.—Messrs. Bakers, Godfrey and Sons, Isaac House, K. and E. Hopkins, H. J. Jones, B. Ladhams, Reamsbottom and Co., and W. Wells, jun.

Shrubs.—Messrs. J. Waterer Sons and Crisp, John Klinkert, and G. Reuthe.

Violets.—Messrs. J. J. Kettle and B. Pinney.

ORCHIDS.

AWARDS OF MERIT

CATTLEYA MIMOSA VAR. GRANDIFLORA (Venus × triumphans).—One of the finest hybrids derived from Cattleya bicolor. The large flower had the sepals and petals of bright golden yellow colour, slightly tinged with bronze, the flatly displayed labellum of plum-purple colour, and with its side lobes enveloping the whitish colour. A noteworthy feature is the thick texture of the whole flower, while the broad petals, with their prettily crisped margin, are developed to an extent seldom seen in this section. Shown by Messrs. Cowan and Co., Southgate, N.

VUYLSTEKEARA EDNA, STAMPERLAND VARIETY, obtained by crossing Miltonioda Harwoodii with Odontioda Charlesworthii, and thus combining the three genera—miltonia, odontoglossum and cochlioda. The elongated spike bore nineteen flowers of medium size, reddish scarlet in colour and of a much brighter nature than previously seen. Shown by Mr. Robert Paterson, Cathcart, Glasgow.

LÆLIO-CATTLEYA PROFUSION VAR. MEGANTIC.—Probably the largest and finest form of this popular hybrid. The plant bore a single flower having all its segments of model formation, well above the average size, and of bright rosy-mauve colour, the labellum ruby-crimson with a narrow, lighter tinted margin. Shown by Messrs. J. and A. McBean, Cooksbridge, Sussex.

CATTLEYA LADY VEITCH.—An exceptional variety of this hybrid between C. Lueddemmaniana and C. Warneri, of which albino forms were used, the resulting flower being pure white, except for some yellow in the tube of the labellum. The petals are larger and broader than usually seen in this hybrid. Shown by Mr. H. T. Pitt, Stamford Hill.

NEW AND RARE PLANTS.

AWARDS OF MERIT.

CHRYSANTHEMUM JAMES BAXTER.—Shown by Mr. W. Baxter, The Gardens, Lockerby Hall, Romsey. Described under "New Chrysanthemums."

CHRYSANTHEMUM MAYFORD YELLOW.—Shown by Mr. H. Shoesmith, Woking. Described under "New Chrysanthemums."

COLLETIA SPINOSA VAR. ROSEA.—This representative of the Rhamnaceæ only differs from the type which received an award in 1904 in the possession of rose-coloured flowers which give the varietal name. The spines are characteristic. The sprays shown were wreathed in the small blossoms, and the shrub should prove a valuable one for decorative effects. Shown by Messrs. R. Veitch, Exeter.

ARBUTUS UNEDO RUBRA GRANDIFLORA.—Sprays of this fine varietal form of the strawberry tree showed off to advantage the deep pink flowers which stand out conspicuously against the dark background of foliage. This would appear to be a fine ornamental and graceful tree when well grown, with its clusters of flowers and fruits. Shown by Messrs. Gill and Son, Falmouth.

BERBERIS JAMIESIANA.—This is a fine species and appears to be closely allied to B. polyantha. With its long arching reddish brown stems and its clusters of dull red berries, combined with its golden brown tinted foliage, it is an exceedingly attractive species. Shown by the Director, R.H.S Gardens, Wisley.

MYRTUS UGNI.—This is a Chilian representative of the myrtle family, with evergreen, rather leathery, oval leaves resembling those of the ordinary myrtle, but with smaller flowers. The fruits are of a glossy reddish black in colour and are borne on single dangling stalks arising in a cluster. Shown by Mr. G. Reuthe, Keston.

BOMAREA WHITTONII AND BOMAREA MATTHEWSII.—These are two interesting hybrids raised in the Glasgow Botanic Gardens, and are the result of crossing B. edulis and B. Carderi in the first case and reversing the parents to obtain the second hybrid. Both show a considerable improvement on either parent and should prove valuable additions to our list of cool greenhouse plants. The leaves of B. Whittonii are about 3ins. long and of a light green colour, with the characteristic twist. The long bell-shaped flowers are of a delicate rose colour on the outside and spotted brown on a cream ground inside. They are borne on long pendulous stalks. B. Matthewsii has much larger and darker leaves, almost 6–7ins. long, and the flowers are also of a darker shade of dull pink and are carried on much longer stalks. Both are handsome forms and are sure to find a place in the cool greenhouse, once a supply is available. Shown by Mr. G. Banks for the Director of Parks, Glasgow.

VIBURNUM THEIFERUM.—This is a handsome species from western China and was introduced by Wilson in 1901. It bears medium-sized tapering leaves with widely toothed edges, and from the sprays shown, fruits exceedingly well. These are borne in rounded clusters and hang gracefully from the branches. They are bright red in colour and rounded to egg-shaped. Shown by Mr. G. Reuthe Keston.

ASTER QUEEN MARY.—A fine variety of the Novi Belgii type with fairly large flowers of about 2ins. across. The ray florets are upstanding and incurve over the yellow cushion-headed centre. Shown by the Hon. Vicary Gibbs, Aldenham (Mr. E. Beckett).

NEW CHRYSANTHEMUMS.

On October 19th last the Floral Committee of the National Chrysanthemum Society made the following awards to new varieties:

JAMES BAXTER.—A very desirable exhibition Japanese variety. The very shapely flowers have broad drooping florets of deep old rose colour flushed with crimson in the centre. First-class certificate to Mr. W. Baxter.

MAYFORD YELLOW.—A valuable market variety of medium size and made up of stiff yellow florets. First-class certificate to Mr. H. Shoesmith, jun.

GARDEN TECHNIQUE

Notes on the Technical Side of the Garden and the Cultivation of Plants.

SEAKALE.

IF very early supplies of this vegetable are required, a quantity of roots, which are full of food material, should be lifted from the beds now. Good strong crowns should be selected, and the large thongs—or side roots—taken off. These thongs or whips may be notched into lines in some part of the reserve garden, or set in boxes of soil and covered over to the depth of 3ins. or 4ins. with fine ashes. The bottom portion of each small rootlet should be cut in a slanting direction, if there is likely to be difficulty in recognising the top ends. Thus vegetative propagation as a method of increasing the stock may be so arranged as to go on simultaneously with forcing preparations.

The large roots should be set a few inches distant from each other among fine soil or leaf-mould in the forcing house, then after a good watering they should be kept in darkness. Blanched stems should be ready for cutting in from four to five weeks time from date of placing roots in heat.—DAVID ARMSTRONG.

THE VALUE OF ANNUALS FOR EARLY FLOWERING.

ANNUALS now form a very important feature of the garden, whether the latter be large, medium or just a tiny plot. Probably they have been grown more generally in the small, than in the large garden in past years, but they are general favourites now and everybody wishes to have their flowers available for as long a period as possible. With this object in view seeds should be sown in the autumn in pots, boxes and cold frames. Statice sinuata, usually sown in the spring, may be sown in November, where there is a glass structure available, the seeds soon germinate and the resultant seedlings should be left undisturbed till February then they should be transplanted in boxes or frames or singly in small pots. The time to plant in the flowering quarters is mid-April. Almost at once, if the work is well done and the soil in good condition, the plants will begin to grow and early flowers will soon be available. To prolong the season to October spring sowings should be made. Calendula officinalis Orange King may be grown in a similar way; the seeds will germinate in any month under glass. Spiral candytuft is also easily grown and flowered in pots or boxes; the seedlings should be thinned out, not transplanted. Annual larkspurs are charming and may be had in bloom two months earlier than usual by sowing seeds in small pots in January and transplanting; follow these by sowing Godetia Lady Albemarle, dwarf and very free, in February. These with Ten-week stock, mixed, will afford a wonderfully bright display of flowers in a warm border many weeks before blossoms can be had from ordinary spring sowings.

THE DISTURBANCE OF PLANTS

SEVERAL years ago Sir Isaac Bayley Balfour said that theoretically the best way to grow a rhododendron was to sow one seed in the exact place where you hoped to see the plant reach maturity. By that he meant that the less you disturbed the root action of plants the better. Like in everything else, there are certain exceptions, but we move our trees and shrubs too much; of that I am certain. How often do you hear it said, "Oh, plant it there; it can always be moved afterwards." That is the wrong way to look at the subject. The movement of trees and shrubs should only be undertaken after considerable thought. I was just as careless as anybody else and would move a plant on the slightest provocation; but now I have come to the conclusion that many deaths take place in the garden owing to disturbance of the roots.

It is, perhaps, natural that we are inclined to ignore what we cannot see, and that few of us realise what a check is given to a plant by moving it owing to the disturbance of the roots and the impossibility of avoiding breaking or bruising something in the elaborate system that a plant evolves under the ground. The remedy is to give more attention to the first planting and to realise that a plant cannot be dug up without injury. This is more obvious in the case of plants which make long tap roots like the hickory, the magnolia and the oak. On the other hand, many people, myself included, have said that a shallow rooter like the rhododendron, with masses of surface fibrous roots, is not harmed by transplanting. We are wrong. They are checked, although to a lesser degree than a plant with a tap root. The selection of a poor position —and ultimate transplanting—is often caused by ignorance, particularly in the case of new introductions, and collectors and cataloguers would confer a boon on all gardeners if they would give more details about the soil in which a plant grows for the science of intimate conditions below ground is comparatively new.

From my own experience, I know the great advantage that a plant in an original position has against one that has been transplanted. The plant may not die; it usually does not, but it stands still for a year or more, while time does not wait for the gardener. So the transplanting often costs him one, two or three years of extra waiting.

I would go even further, and say that the ideal method of raising a tree or shrub from seed was one seed one pot—provided, of course, that it was not a community plant where close contact with their kin is a necessity for their welfare; but the ordinary run of trees and shrubs which lead a solitary existence as specimens, or one of a group as opposed to a tangle, would be the better for the treatment of one seed one pot, and one large enough at that to avoid re-potting at an early stage. However careful and however neat-fingered you may be, there is bound to be a certain amount of damage to the young roots, with a consequent derangement of the whole intricate system of a plant's interior structure. One seed one pot saves pricking off and often allows you to grow on a plant in its original pot until it is large enough to plant out, with, of course, a certain amount of new soil added from time to time.

The objection to this system of seed-sowing is obvious—lack of space. Everyone hates to waste any seeds which have been given to them or which they may have bought; but an over-abundance of seedlings is almost more of a curse than too few. You do not know what to do with them and try to grow them all, with consequent lack of attention, instead of burning what you cannot use or give away. This destruction is horrible, but it is sometimes necessary.

Whether you carry your raising of plants to such an extreme or not, it should be realised that all planting should be done as much as possible in the position that the plant will finally occupy. Care should be taken over the selection and preparation of the site, so that when it is in position its roots can get a good grip of the soil and be free from needless disturbance. Changing a tree or shrub from place to place will never do it any good and will often do it harm.

E. H. M. C.

FLOWERS IN LONDON PARKS

EVERY year those in charge of the London parks appear to better the floral displays at all times of the year. This autumn the dahlias have been particularly fine, and have, indeed, become one of the sights of London. Even at the end of October the beds were gay with flowers. Most of the charms were over, but the pom-pons and the cactus-flowered had stood up remarkably well against the weather. The chrysanthemums have also been very fine this year. Five parks have a special show of them: Battersea Park, Waterlow Park, Finsbury Park, Victoria Park and Southwark Park. They are well worth visiting before the hard weather sets in.

A GOLDEN BORDER

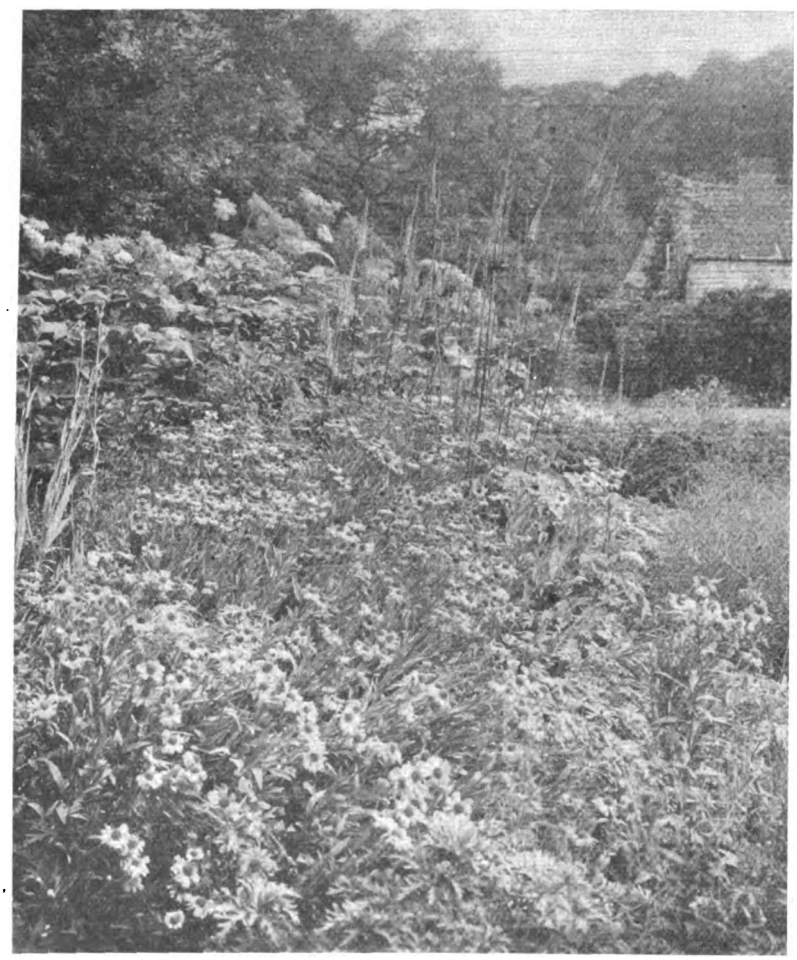
THERE are three different ways of making a "colour" border; in the first, the flowers are arranged to tone from light at one end to dark at the other; in the second the shading is graduated from pale in front to deep at the back, and in the third the various shades are mingled throughout. The last plan is certainly the easiest to carry out and when the key-colour is yellow, it may be safely followed; for all yellows —I think I may say without exception—harmonise with each other, which is very much more than can be said for reds, pinks or blues, especially the latter. Suppose then that the third plan has been decided on. The border may be edged with such spring-flowering plants as Alyssum saxatile alternated with Cheiranthus Allionii or C. alpinus, although the latter, perhaps, is a little too dwarf to combine quite satisfactorily with the alyssum. After flowering, both alyssum and cheiranthus can be cut back and dwarf nasturtiums, mixed cream, yellow and orange, sown between them for succession, or the plants may be lifted and replaced by bedding violas, such as Royal Sovereign, pale yellow; Moseley Perfection, deep yellow; Klondyke, bright yellow; and Tangerine Harrison, orange. But as a matter of fact it is really best to discard the old plants of alyssum and wallflowers replacing them with young ones each autumn, as neither can be absolutely depended upon for a second year's flowering and both are easily raised from seed.

Immediately behind the edging plants may come a broad band of May-flowering tulips, ranging through every shade of yellow, from the pale Leghorn Bonnet to rich-coloured Bouton d'Or. If, however, the border is a long one and the cost of enough tulips to make a satisfactory display is thought too great, quite a brave show will result if such wallflowers as Golden Yellow and Primrose Dame are combined with such a tulip as Mrs. Moon and Inglescombe Yellow, or the paler Moonlight. In due course these may be followed by intermediate antirrhinums, of which Golden Gem and Sutton's Orange King are effective varieties, if the latter is not thought to approach scarlet too nearly to be strictly admissible in a golden border. The buff shades should be avoided, and also the pale and rather sour yellow which seems prevalent among the snapdragons sold by "small" nurserymen. Among the antirrhinums may be placed bold groups of Gladiolus primulinus, in which several good tones of yellow are now obtainable.

We now come to the main part of the border and for the first row of this, plants from 2ft. 6ins. to 3ft. 6ins. in height will be wanted, although the expression "row" must not be taken too literally, as groups of taller things should be brought forward from the rear at intervals to obviate anything approaching a dead straight line. Suitable plants for this, the third, section of the border, are Rudbeckia speciosa, Inula grandiflora, Helenium pumilum and H. Bigelovii aurantiacum, Anthemis tinctoria, Digitalis ambigua, Doronicum plantagineum excelsum, Coreopsis grandiflora, Asphodeline lutea, Helianthus multiflorus Golden Ball, and the yellow lupin that is one of the hybrids between L. arboreus and L. polyphyllus. Clumps of Lilium croceum may be introduced here and there, as well as such shrubs as the golden-foliaged Cassinia fulvida and our native Potentilla fruticosa, a pretty yellow-flowered bush, of which a charming picture was given in THE GARDEN of May 2nd. If the border is sufficiently wide, Berberis stenophylla and B. Darwinii may be added to these.

There are many golden-blossomed plants from 4ft. to 6ft. high, from which a choice can be made for the back portion of the border. Among the showiest are the Rudbeckias Golden Glow and Autumn Glory, Helianthus Miss Mellish, Helenium Riverton Beauty, Heliopsis B. Ladhams and H. Excelsior, Verbascum Chaixi, Centaurea macrocephala and C. ruthenica, Solidago (the variety Golden Wings is, perhaps, the least coarse), and Senecio tanguticus. Lilium tigrinum in groups of six or eight bulbs will add much to the effect, as will the tall spires of yellow hollyhocks, but unfortunately these cannot be depended upon to come true from seed. However, it is worth while to try the experiment of putting in a few plants grown from seed saved from yellow flowers. Finally, the border may be backed with poles—or a treillage—on which are trained Clematis orientalis, with its quaint, golden flowers, like tiny Chinese lanterns, and yellow roses. Of the latter such old favourites as Jersey Beauty, Gardenia, Goldfinch and Albéric Barbier will be suitable, but a true yellow climbing rose sufficiently hardy to be grown outdoors is yet to be found.

If annuals other than the edging nasturtiums are permitted—and they are very useful to fill up those blank spaces which will occur in the best regulated borders—double calendula, annual chrysanthemums, coreopsis, sunflowers (both the tall varieties—yellow primrose and so-called red—and the dwarf ones) annual lupins and Dimorphotheca aurantiaca may be recommended.



HELENIUMS IN THE GOLDEN BORDER.

A slight variation on the border scheme suggested above may be carried out by raising it slightly and edging it with rockery stones, planting behind and among these Helianthemums in shades of yellow and orange, Geum Lady Stratheden, Potentilla Mont d'Or and P. Yellow Queen, and Linum flavum, to which may be added Meconopsis cambrica (which will seed itself freely), Corydalis lutea and Viola cornuta lutea. These plants will form a permanent edging, of course.

PLANTS FOR A GOLDEN BORDER WITH TIME OF FLOWERING AND HEIGHT.

Alyssum saxatile	May-June	8ins.
Antirrhinums (intermediate)	All summer	15ins.

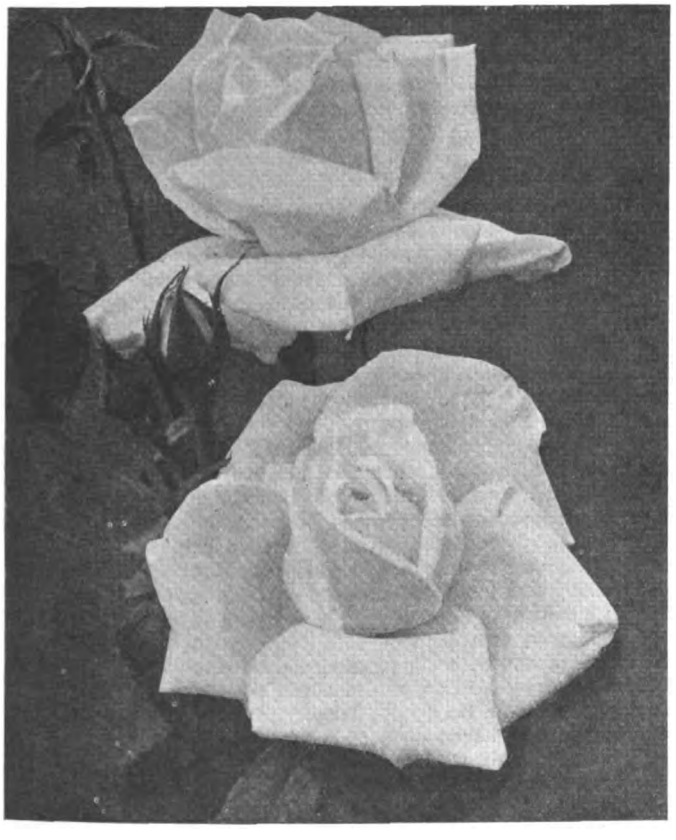
R. E. HEAD.

SOME OF THE NEWER HYBRID TEAS



THE FRAGRANT MARCIA STANHOPE.

INDEPENDENCE DAY, ONE OF THE BEST OF BEDDING ROSES.

THE hybrid teas come apace. Looking through the National Rose Society's "Select List of Roses" for 1925, I find that over 100 varieties, which have been introduced between the years 1916 and 1922 inclusive, are considered worthy of recommendation for one reason or another. Bearing in mind that many which perhaps appeared in the list five years ago have been eliminated and many more have never found a place, we can realise what a tremendous output of new hybrid teas has been made during the last decade. We obviously cannot grow them all, yet to choose among so many would seem bewildering.

Beauty of form and the lasting quality of the individual bloom, the vigour and hardiness of the plant itself, may not be greater in the rose of 1925 than it was in that of the pre-war roses. But even so short a time ago as 1915 there was little in our rose gardens that could compare for sheer brilliancy of effect with a bed of such later varieties as K. of K., Hortulanus Budde, Red Letter Day, among crimsons; Golden Emblem, Mabel Morse and Christine, among the yellows; while such colours as the almost pure orange of Independence Day, Emma Wright and Severine; the vivid cerise orange and flame tints of Henrietta, Padre and Betty Uprichard and others, were only just finding their way into our gardens, through the introduction, in 1913, of the still almost universally grown Mme. Edouard Herriot.

Even these bright tints will pale before the still more vivid hues of Elvira Aramayo, Eva Ekins and Mr. McGredy's gold medal rose, Margaret McGredy. Possibly we have gone far enough in the direction of brilliancy of colour, which may degenerate into hardness and gaudiness, and that it will be well to give greater attention to beauty of form and outline, to fragrance and to hardiness and immunity from disease.

Los Angeles (Howard and Smith, 1916).—If I were only allowed to plant one hybrid tea introduced during the last ten years, I should unhesitatingly choose this. It grows into a tall, upright bush and produces large blooms of the most delightful fresh apricot, with a warm glow of coral rose in the centre; the petals are of excellent substance, and if only it

Digitized by Google

would always hold up its head (it sometimes will) there would be no fault to be found with this variety. With us it has grown and flowered well on tall standards budded on the rugosa stock, as well as when grown in bush form on the briar.

W. F. Dreer (Howard and Smith, 1920), is a sport from Los Angeles. It is not so tall a grower and is apt to have rather a sprawling habit. The beautiful flowers of sunset tints, yellow, peach and apricot, are produced freely on smooth stems and though the branches are less upright than those of Los Angeles, the flower stalks themselves are firmer.

Independence Day (Bees, 1919).—All through this summer our batch of Independence Day has flowered well and freely. The golden orange flowers, though decidedly thin, are always well shaped and delightful in colour and pretty in all stages of development; they are held quite erect and stand even heavy rain without discolouring. The foliage is bright, polished green. This is really a Pernet variety, but the Pernet roses are now so much inter-crossed with the hybrid teas that I am writing without making distinction between the two classes. Independence day is certainly one of the best roses we have for small or medium sized beds. It is not tall enough for the big beds, such as we see in Kew Gardens.

Emma Wright (S. McGredy and Son, 1917), is a beautiful little rose of a much deeper orange than Independence Day, also with polished foliage. It is not, however, nearly so free-flowering. It is a great favourite for table decorations, the colour being good and pure and lighting up well. It is little more than semi-double.

Mrs. C. V. Haworth (A. Dickson and Sons, 1919), is another semi-double variety with many tints of yellow, peach, salmon and pale rose on its petals. At the latter end of June it was one of the most effective and floriferous of the roses in the Trial Garden at Wisley. Some growers complain that it has a way of dying out, but we have not had this experience in our garden.

Mrs. Dunlop Best (Elisha Hicks, 1916), is one of the hardiest and most vigorous of the newer hybrid teas. It has delightful and rather unusual foliage, dark green with a little kink at the edges of the leaves, which almost remind one of holly leaves without the prickles. The flowers this year have often been of a deep orange with a touch of reddish bronze. Other years I have not noticed them as being quite so good in this matter of colour, and should have described them as deep buff. This is a rose that can be recommended for general garden cultivation.

Ruth (Pemberton, 1921) is an appropriately named rose. Its delightful golden orange blooms are flushed with apricot and rose, their colouring as well as their name suggests a field of ripe corn at sunset. If only the bloom had an efficient stalk to show off its beauty, this would be an excellent rose for beds, but unfortunately it far too frequently hangs its lovely head.

Among the cerise coloured roses there are two of outstanding merit, both brought out in the same year by the same firm, Betty Uprichard and Lady Inchiquin.

Betty Uprichard (A. Dickson and Son, 1921), is a rose of wonderful colouring, bright deep cerise on the outside of the petal and salmon pink on the inside, though the flowers are thin they are freely produced on straight stems and the plants are hardy and of good habit. This is quite one of the best and most popular of the newer hybrid teas.

Lady Inchiquin (A. Dickson and Son, 1921), which is classed by the N.R.S. as an exhibition variety, has full, well shaped blooms of pure cerise pink. The plants are only fairly vigorous and only moderately free; they are given to mildew, but it is worth growing for the sake of its colour and form.

Shot Silk (1924), is another variety with good form and lovely tints, difficult to describe; soft cerise suffused with salmon and gold gives only a suggestion of the colour. The shape, too, of the bloom is quite good and it is held erect on a stout, if rather short stem, and moreover, has a delicious scent.

The two best roses of the Mme. Edouard Herriot colour are *Henrietta* (Merryweather, 1917), and *Padre* (B. R. Cant, 1920). Neither are so free flowering as the earlier rose, but they are of a softer terra cotta and are not so given to stem mildew. Of the two I prefer Henrietta.

Mme. Butterfly (The E. G. Hill Co., 1920).—A sport from Ophelia, is so well known that it needs no description. For the open garden it is, in my experience, a better doer than Ophelia, though, like that variety, and Ophelia's pretty creamy white sport, *Westfield Star* (Morse, 1920), it needs constant attention in disbudding if we want the almost perfect shaped flowers which these three varieties are capable of making. They are all very fragrant, and all have smooth, firm flower stalks.

Marcia Stanhope (C. Lilley, 1922), is said to be a seedling from Frau Karl Druschki. The white and delightfully fragrant flowers do somewhat resemble the older variety, but they are not so freely produced nor so perfect in shape.

The thought of fragrance brings me to consider the newer red roses, which, unfortunately, too often lack this quality.

The brilliant *K. of K.* (A. Dickson and Son, 1917), the deep plum red *Covent Garden* (B. R. Cant, 1919), and the fine crimson *Lord Charlemont* (McGredy, 1922), are all worth a place in the garden, but all are sadly wanting in fragrance.

For this quality we must go to *Etoile de Hollande* (Verschuren, 1919), a dark crimson, with a very rich scent, and *William Baver* (Chaplin Bros.), also a dark red fragrant rose; it is not quite so well shaped nor so free flowering as Etoile de Hollande.

Hortulanus Budde, a bright scarlet crimson with a yellow base, which gives a wonderfully brilliant effect to the somewhat thin, but very freely produced flowers, and *Miss C. E. van Rossem* (van Rossem, 1920), with small, well-shaped, dark crimson and moderately fragrant blooms, are good bedding roses.

Two new fragrant crimson roses have been shown this year; these are *George H. Mackereth* (A. Dickson and Sons, 1924), and *Arthur Cook* (S. McGredy and Son, 1924). Both have the real old rose scent and are of a dusky crimson hue.

I must not finish these notes without mentioning three good pink roses.

Charles E. Shea (Elisha J. Hicks, 1916), has well shaped rich pink flowers with a suggestion of salmon.

Mrs. Henry Bowles (Chaplin Bros., 1921), is a strong grower and produces abundantly its large, full rose-coloured blooms throughout the season.

Columbia (The E. C. Hill Co., 1921), is also very free. Its flowers are a true pink, are full and fragrant, and are held erect.

WHITE LADY.

FLOWERING SHRUBS in the HERBACEOUS BORDER

BY GERTRUDE JEKYLL.

THE term "herbaceous border" is generally used for any border where flowering plants, mostly hardy perennials, are grown in combination. It should be accepted and used with a good deal of elasticity, for a certain number of the border's occupants, such as pinks and the broad-leaved saxifrages, and grand things such as yuccas and phormium, are by no means herbaceous. Also it may include a number of summer bedding plants and a good many annuals which are also not at all herbaceous. A further demand for latitude presents itself when we come to certain shrubs which may well be made welcome in the flower borders. The occasional inclusion of shrubs towards the back gives a pleasant impression of solidity and permanence, especially if the border is of large proportion, and they take their places finely in good colour arrangements.

Thus, if a border begins at one end with plants of cool and tender colouring—blue and white and palest yellow—there will be the place for a bush of Ceanothus Gloire de Versailles. Pruned hard back every winter it makes a multitude of flowering shoots that are beautiful in July and August and are delightful with white dahlias and hollyhocks, tall white snapdragons and the white everlasting pea that covers the half cut down delphiniums that were in beauty three weeks earlier. Another delightful shrub in this region is Hydrangea arborescens grandiflora, blooming at the same time at the point of every twig. It is kept to under 5ft. and comes a little more forward in the border. The colour now passes on to yellow, and at the back are some bushes of golden privet, trimmed to the height and size desired. This constant pruning prevents flowering, so that the unpleasant smell of the bloom

Digitized by Google

is avoided. All through the summer this group of golden foliage shows as nearly the brightest yellow in the border. It is accompanied by the cream-coloured blossom of Artemisia lactiflora, which is grouped with the pale yellow annual sunflower. Following this is yet another bright yellow-leaved shrub, the golden elder, also closely cut back in winter, when it throws up a showy head of large yellow leaves. The tall Rudbeckia Golden Glow is planted close to its foot and is brought up through it, making it look as if the yellow blossom belonged to the golden bush.

Where there is a gorgeous mass of red colouring in the middle region of the border's length there are some bushes of Prunus Pissardii forming an harmonious grouping with claret-coloured and richly deep red and blood red hollyhocks and a tall old dahlia of something even deeper than claret colour. This deep coloured filling to a mass of red dahlias and cannas is continued forward by the red tinted Ricinus Gibsoni, and more forward still by iresine and a red-leaved amaranthhus. Then come the yuccas, the tall Y. gloriosa and the dwarfer-growing Y. filamentosa. Here the colouring is again white with palest yellow, and here is a group of Hydrangea paniculata. The ordinary pink Hydrangea hortensis is freely used for dropping in to any empty spaces such as occur from the removal of a group of the biennial clary towards the end of the border. Here the colouring is of pink and purple flowers with grey foliage, so that excellent small shrub Senecio Greyii finds a place, with bushes of the silvery-leaved Hippophæ (sea buckthorn) at the back. This stiffening of a large flower border with shrubby growths is much to be advised. A number of other shrubs could be used in the same way, such as the neat-looking Veronica Traversii at the back and smaller veronicas towards the front. The pretty blue Plumbago capensis is a delightful thing for dropping in in the region of blue and white flowers.

HYDRANGEAS IN THE WILD GARDEN

BY H. AVRAY TIPPING.

NEVER before I recently made this garden in Monmouthshire had I had one where the hydrangea family flourished. Thus, I am only beginning to be on intimate terms with it and to note its curious eccentricities. You buy a variety, with a bloom said to be of a certain colour, but you haven't the least idea what trick it is really going to play you. It may prove a very chameleon—not, indeed, assimilating to its environment, but using the soil it happens to be set into as a pigment to deck itself out in most varying hues. Of course, I knew and had seen how a pink hydrangea was often blue in Devonshire; and among Mr. Jones's enormous numbers of varieties, as he stages them at Chelsea, a great many colours appear. But the capacity of a single variety, nay of a single plant, to form half a rainbow, has come upon me with a little surprise. On the limestone of Mounton House, a dozen miles from here, hydrangeas out of doors did no more than eke out an existence, and the only variety I could be pretty sure of getting to bloom was Souvenir de Mme. Cherau. Whereas, the old hortensis is a pale and rather characterless pink, Mme. Cherau at Mounton was of a full, rich, strong rose or cerise colour. It also is the one which is most dependable for out-door blooming here, where, right up in the hills, the season is often not warm enough to bring plants that have been cut back by one winter into blooming stage before the next one sets in. I therefore have lots of it about, and this one variety might be a legion from the colour variations it presents. There is a three year old plant on the terrace that has a dozen bloom heads, none of them quite similar. One is just exactly the cerise that I knew of old, while others are more or less violet or blue, but never fully the latter. In the wood it is never cerise, but often blue, and in some cases the blue, as a blue, is just as full, rich and strong as the cerise. The two best plants were already two year olds when I planted them three years ago, and the illustration shows what sizable and floriferous plants they now are. But, of course, the effect they produce can in no way be realised in monochrome. The blue of them really quite startled me, when, after some months absence, I came down here and caught sight of them at the end of July, six weeks before the photograph was taken. With the rich blue, there is here and there a suffusion of deep purple. The effect is somewhat metallic, rather like the blue of tempered steel, but with added intensity and the charm of variety that nature knows so well how to give. There has been no dressing given for this purpose. It is entirely the effect of the natural soil in that quarter of the grounds. The ordinary hortensis, close by, is only more or less pale blue, and, as I have described its pink, characterless. I strongly advise those whose soil favours the blue of hydrangeas to plant Mme. Cherau freely. And that is very easily effected, for few shrubs give quicker results than hydrangeas. By cultivating some in pots we have a double-flowering season. We like a few in the spring, but as August and September are the chief residential months here, we like plenty for the house at the same period as they bloom outside. Thus, of last year's cuttings, a batch was kept back and has only just come into flower. All tend towards a blue colour from our ordinary potting soil, but are much lighter and more suffused with violet than the old plants in the wood. The plants are about 2ft. high, the bloom heads measure 2ft. round, and there are leaves 9ins. long and 6ins. across, thick in substance, deep green in colour. You imagine them with prodigious roots, sucking up their substance from half a bushel of soil. But no, they have just remained in their tiny 4in. pots, so that they give you the idea of the noble Chinese ladies of old whose feet were never allowed to grow beyond a five year old's size. The little pots are so crammed with fibrous roots that there is practically no soil. Unlike a human being, the hydrangea seems able to

A FINE BUSH OF HYDRANGEA SOUVENIR DE MME. CHERAU IN THE WOODLAND.

Digitized by Google

live on concentrated essences, without substance. Clay's fertiliser seems to be the vegetable "Bovril" that grows them great and maintains them in robust, almost athletic health.

But we also have some two year old plants in pots. For this late summer blooming these were cut down to near the ground in spring. They were set some in 7in. and some in 8in. pots and allowed either two or three shoots. They are now over a yard high and have the biggest leaves I have ever seen in hydrangeas, up to 10ins. long and 8ins. across. But the bloom head should surely satisfy the most ambitious Yankee, who could swell with pride as he called them the greatest in the world. Here we have one 3ft. 9ins. in circumference, 1ft. 2½ins. across the base, and 2ft. 1in. over the dome-like top. It is of the old hortensis variety and pale blue in colour, but its neighbour, a chip of the same block, with the same treatment and reaching the same proportions, is pink.

Many people no doubt have the same history to tell, and with more detail and experience than I possess. All I have said is merely the usual expression of surprise of the beginner in any study.

ON MICHAELMAS DAISIES—I

SOMEHOW I like the designation Michaelmas daisies far better than starworts, although this last name can boast the usage of British antiquity. Starwort or starflower seems more appropriate for yellow flowers, and, as far as I know, there are no yellow Michaelmas daisies or asters. The charming little pale yellow so-called Aster luteus is, properly speaking, a solidago. The only inappropriateness of the name would arise when flowers are admitted into the confraternity which do not flower about Michaelmas.

Modern lists admit the oldest garden section of all—the Amellus. Quite rightly, I think. They can point to the present "late" year of grace for their justification. I have some Amellus varieties in my garden which have not put forth a single bloom even to brighten our autumn oasis, St. Luke's little summer! Moreover, it is now a growing section. Roughly speaking, it remained a sort of Peter Pan for three hundred years. It had to wait for the touch of the twentieth century before bursting out into an unsuspected loveliness. Those who welcomed Benarabicus as an improvement on the typical Amellus can appreciate the change the creation of the modern varieties like Beauty of Ronsdorf, Wienholtzi and King George has brought about. I know little about their raisers. The names of many suggest a Continental origin; but if neither a Beckett nor a Ballard have given them to us, they are, nevertheless, heartily welcome in our gardens. We thank our good neighbours for working while we slept. We are, however, waking up. When I visited Mr. Ballard at the end of September he told me he was seriously thinking of taking them under his wing. For readers who do not know them, it should be said that the race is characterised by a low-growing habit (only 2ft. or less) and large flowers after the type of Ballard's new October Dawn. They are practically immune from mildew; they require little or no staking; and a few like grandis and Wells' Favourite are unselfishly sweet-scented. It is delightful to stand near them on a sunny day. As far as I know, no Novi Belgii or Novæ-Angliæ does this. If they have a slight scent they keep it to themselves. From the above everyone can judge for themselves if the type will suit them or not. It only remains for me to point out a few varieties which especially appeal to me and to others who have seen them here this autumn. With but one exception I grow them all, and so I am able to write from first-hand knowledge, without, I trust, putting my list forward as one issued with any air of infallibility. As I have found the names a little uncertain, I append the source from whence the different varieties came.

THE RICH DEEP BLUE FLOWERS OF ULTRAMARINE.

ADVANCE (Wells).—Large pale purple, early flowering, very free.

BEAUTE PARFAITE (Jones).—Large centre, one of the bluest toned.

BEAUTY OF RONSDORF (Jones).—Fine habit, large flowers of a pretty pinky mauve with a deep halo round the centre, very distinct.

CASSUBICUS (Jones).—Rich purple with dark centre.

GRANDIS (Perry).—Large pale mauve flowers, sweet scented, early, very fine variety.

OTTO RUDOLPH (Jones).—Tall, dark centre, deep colour.

PREZIOSA (Jones).—A redder shade of deep purple than Ultramarine, excellent habit.

RUBY (Bones).—A lovely shade of rose pink, very solid looking, tall, early flowering.

RUDOLPH GOETHE (Jones).—Similar to King George in colour, but a nicer habit, large.

ULTRAMARINE (Jones).—Tall, rich deep blue-purple, small flowers.

WELLS' FAVOURITE (Wells).—The best of the rose-pinks, sweet, tall and early.

WIENHOLTZI (Jones).—I have not grown this, unless the presence of a stump and root which never made any attempt to function makes a sufficient claim. All the same, whenever I have seen it the beautiful pink colouring of its flowers gave me a sense of supreme satisfaction. I fully share the cataloguer's enthusiasm.

With the Editor's permission I hope to devote the whole of my next article to longer or shorter notes on the great Novi Belgii section. It is, and probably always will be, the most important one as far as garden decoration is concerned. It reaches in height from Little Boy Blue and Esme to King of the Belgians; in colouring from Purple Emperor to Maid of Colwall and White Climax; and seasonally from Lavender and Phyllis to Belgian Queen and October Dawn.

What can you wish for more, my boys,
What can you wish for more.
(An old pantomine refrain.)

JOSEPH JACOB.

EARLY FLOWERING CHERRIES

BY COLLINGWOOD INGRAM.

WITH the advent of summer, when our gardens are ablaze with colour, we are liable to forget the first few flowers that thrilled us in the spring. Yet there is none that annually gives us so much real pleasure as these, for do they not come after long, weary months of waiting—dark and ugly months, during which our senses have been hungering for their beauty? Prose and poetry alike have sung the praises of the more humble harbingers of spring—the snowdrop, primrose and daffodil—so it is not of these that I intend to write, but of some of the lesser known, though none the less beautiful, cherries of the Orient.

One of these, the Japanese Prunus subhirtella autumnalis, commences to flower in November and continues undaunted by the coldest weather, to open its semi-double, pinkish-white blossoms throughout the winter—not in ones and twos, but in masses! Even if an unusually severe snap damages the flowers, they are soon replaced by a fresh crop. Then, in late February or early March, comes the Chinese species, P. Conradinæ, with its white or pinkish flowers. The petals of the single form are inclined to be somewhat fugitive and for this reason the semi-double, pink variety is a more valuable plant. Although paler when open, in the bud stage these flowers are of a vivid *cerise* pink, and are then particularly ornamental. The rosebud cherries, both in the ordinary and weeping forms, are very beautiful little trees, but as they are comparatively well known, they need no praise from my pen. P. incisa, however, is still unaccountably scarce in Western gardens and is unknown to many. Yet this little wilding from the slopes of Fujiyama is an altogether delightful species. It is prodigal with its dainty flowers and even in a shady situation these will wreath the boughs from end to end. Its foliage, too, is attractive, the leaves being as small as those of a birch and so deeply incised that they appear to be ornamented with a prettily frilled margin. This cherry, the Mame Zakura, or pigmy cherry of the Japanese, is perfectly hardy in England and appears to have a very accommodating constitution, for it thrives with me equally well in either sunshine or shade. It is the species generally, though not invariably, used for dwarfing purposes by Japanese gardeners and is therefore apparently amenable to pot culture. As it fruits freely in this country and is quite easy to raise from seed, there can be no excuse for its rarity in this country.

Another early-flowering cherry is P. Yedoensis—sometimes called the Tokyo or Yoshino cherry. With the Japanese themselves it is immensely popular and no variety has been so extensively planted in the neighbourhood of Tokyo as this quick-growing and highly ornamental form.

THE YOSHINO CHERRY, PRUNUS YEDOENSIS.

As a rule quick-growing varieties are not, in their early stages, so floriferous as the more stunted forms, but P. Yedoensis appears to be an exception to this rule. The extraordinary profusion of flowers that may occur on even a young plant six or seven years old, is clearly shown in the accompanying illustration. The blossom is of a delicate shell pink and when massed on the tree is of exquisite beauty. It forms a striking tree with its horizontal branches garlanded with blossom.

NOTES OF THE WEEK

ANTIRRHINUMS — SOME POINTS ABOUT AUTUMN SOWING.

THEORETICALLY, autumn-sown antirrhinums should invariably be superior to those which are sown in spring; actually, a good many disappointments and partial or total failures are experienced, and it is no uncommon occurrence for spring-sown plants to outpace the autumn sown.

Recognition of a few simple facts will enable the raiser to avoid the various causes of failure, and it is well worth while to exercise proper care in handling one's seedlings, for the advantages that can be obtained by using autumn-sown antirrhinums really are very considerable. Common causes of failure are too much nursing, or "coddling," as the gardener terms it, too soft and rich a soil in the seed bed or the boxes used, overcrowding, and, finally, stunting the plants before bedding out in spring.

Where one's garden is of porous, gritty and well drained soil, and where the atmosphere is not heavily smoke laden, there need be no hesitation over sowing antirrhinum seed in the open any time between the end of September and mid-November, and it may be noted that small seedlings almost invariably pass through the winter more satisfactorily than larger plants with a considerable amount of soft stem and foliage. Early sowing is, consequently, by no means an assured method of avoiding failure.

Mother Earth is a far better bed for young seedlings than the most carefully prepared compost in a box, and outdoor sowing is to be strongly recommended except where stagnant damp or a polluted atmosphere discounts the advantages. Obviously, a seed-bed requires to be clean, both in regard to weed seeds and ground pests, but it should not be rich with manure.

Those who have to contend with the disadvantages of wet, heavy soil or smoky atmosphere will be driven to protect their seedlings, but they will be well advised to make up a well drained bed of porous soil in a cold frame in preference to sowing in boxes and wintering the seedlings in a heated greenhouse. Sow seeds very thinly, because it will be necessary to allow the young plants to remain undisturbed until the new year has spent several weeks, and anything approaching overcrowding in the seed-bed is distinctly detrimental to proper development.

The frame should seldom be closed entirely, and on clear fine days the lights may with advantage be drawn right back for a few hours. There is no advantage whatever in encouraging development of big top growth, the one necessity being to secure good roots and stiff, stocky stems.

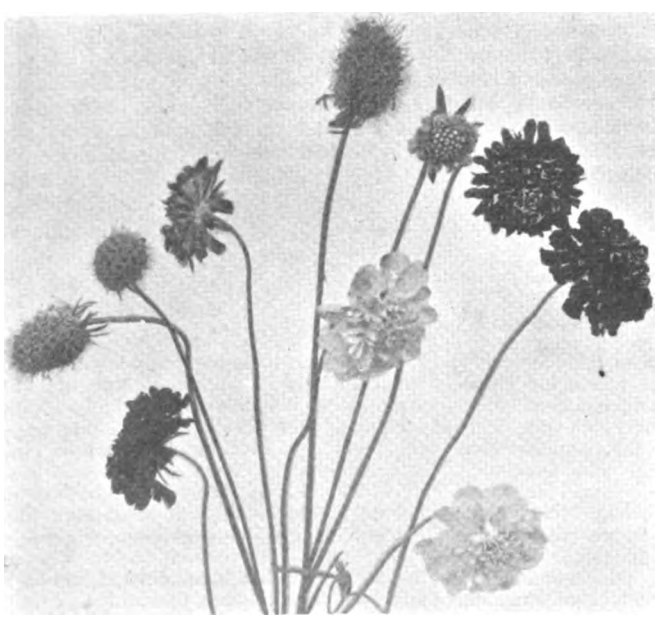
Among the tall growers which are particularly serviceable for the latter purpose and also for grouping in the herbaceous border The King is one of the brightest and best. Orange scarlet with a suffusion of yellow and white tube is its colour description. Yellow King is the best of the yellows

TIGRIDIAS IN A KENTISH GARDEN.

in the tall section, and Monarch is a grand crimson. Rose King provides a deep rich rosy pink on spikes a yard high.

The most serviceable of all antirrhinums are the intermediate, which range from 18ins. to 2ft. in height. Appleby Matthews is a very beautiful variety, orange terra-cotta with white tube, a plant of excellent habit and producing a large quantity of fine spikes. Charm is well named, for its rose pink is of a delightfully soft pure shade, and the plant is of superb habit. Empress is extremely good as a rich velvety crimson,



A CLUSTER OF PINCUSHION FLOWERS.

and Mrs. R. F. Felton is a scarlet self of first-class quality. For delicately tinted and suffused colours Sybil Eckford is enchanting, and Estelle is one of the apricot salmon class which is to be strongly recommended.—A. J. M.

TIGRIDIAS.

THOSE gardeners who love to grow the more uncommon plants will find in Tigridia Pavonia a plant well worthy of their attention. Although it has been in cultivation for many years, this gorgeous Mexican plant is rarely seen, although bulbs can be procured at a very reasonable price.

The plant is a member of irideæ, and, like most of the members of that order, the flowers are of a fugitive nature. The tigridia has leaves up to 18ins. in length and sends up its flower spathe to 2ft. A single flower opens on the spathe every second day. It is open by 9 a.m. and over by 5 p.m. The spathe will continue to give blossoms for some weeks and thus the plant is showy over a long period. A bed of tigridia bulbs planted in March, in my garden, gave the first flower in the middle of July. At this date, September 24th, flowers are still opening.

Cultivation entails no special labour. The bulbs should be planted, 6ins. apart, by the end of March. To ensure safety they should be lifted in the autumn and stored in a slightly damp condition, where frost will not reach them. They will stand a mild winter out of doors with a little protection, but it is scarcely worth risking. The plants can be raised from seeds to the flowering stage in two or three years. There are several variations in colour, from pale yellow to deep crimson. A good flower measures 6ins. across. The spathes may be cut and the flowers will open out in water at the appointed time. The weather does not appear to have much influence in the opening of the flower. Whatever the state of the weather those spathes due to open a flower, do so. I cut some spathes and placed them in a dark, cool cellar for twenty-four hours before the flowers were due to open. The treatment did not retard flowering, even for an hour. — E. BROWN, *Sittingbourne*.

PINCUSHION FLOWERS.

"THE Old English name of Pincushion Flower," so Robinson tells us, "from the resemblance of the flower-heads to that useful article, is perhaps a little more appropriate than it is elegant, although it serves its purpose very well, and, indeed, we have been told these plants are known by no other name in the country." But surely Pincushion Flower is a good deal more elegant than scabious, which, on referring to the Oxford Dictionary, I find means "scabby, affected with mange, itch, etc." In fact, these plants have long been used for curing these various complaints. As usual, Culpeper informs us how the scabious is used to cure most ills, and it is only after a long list of diseases for which this plant is good, that we come across its special use. It is important, first of all, to note that "Mercury owns this plant," and that "the juice or decoction drunk, helpeth scabs and breakings out of the itch, and the like. The juice, also, made up into ointment and used, is effectual for the same purpose."

So much for the origin of the name and the ancient uses of this plant. There are three distinct species growing wild in these islands. Of these, perhaps, the smallest and most insignificant, the so-called Devil's Bit scabious, is the most interesting. It gets its curious name from the appearance of its root when pulled up. It looks just as if it had been bitten off. Botanically the scabious belongs to the teasel family, quite an interesting family to belong to, for was not the teasel used for finishing woollen cloth long before the days of modern machines? For this reason the teasel forms part of the arms of the Cloth Workers' Company.

Of garden pincushion flowers there are several species, but only two of them are of much interest or importance, S. atro-purpurea and S. caucasica. The former, either an annual or a biennial, the latter a true perennial. Both are easily raised from seed. The Caucasian flower grows readily on a nice warm soil, but perishes if the soil be at all cold.

Of all flowers there is none that exhibits greater beauty of bud, flower and seed than does the scabious; the bud, with its unopened florets arranged in neat, concentric rings, slightly pushed up in the centre and surrounded with an irregular collarette of nice dark green bracts; and the flower, with its separate florets, opening from the periphery inwards towards the centre. The larger florets are on the outside, the smaller crowded closely together, imparting a beautiful domed appearance to the flower. The white tipped pistils, which project from each floret, are evidently the pins in the pincushion, which has given these flowers their quaint country name.

Then, lastly, there is the seed pod, no longer dome-shaped, but elongated like a large acorn, covered with reddish spikes, each little calyx forming part of a highly decorative pattern.

What a wonderful improvement on the scabious of our fields and hedgerows is this florists' flower! The huge blooms are borne on sturdy, springy stalks, the whole plant standing some 4ft. or 5ft. high. The flowers are of every imaginable shade, light blue, mauve, lavender, maroon, pink, wine colour, violet, white, some all of one colour, others with beautiful blending shades or sharply contrasting colours. Among a number of plants there always seems to be some new colour or combination to be discovered. The flowers, too, possess a curious sweetish odour, somewhat resembling that of honey.

Pincushion flowers are of easy culture. In order to obtain blossom the first summer after sowing, this operation must be done early, about March. The flowers will thus brighten the garden when summer is on the wane, passing into autumn, filling a gap between the summer flowers and those we are accustomed to associate with autumnal days, such as the dahlias and the Michaelmas daisies. Grown as a biennial, the seed should be sown in May or even later to produce plants which will be at their best early in August the following year. They are best planted out in their flowering quarters in the spring and should be carefully tied to stakes as they grow, to prevent their straggling along the ground as they are only too prone to do. The perennial scabious from the Caucasus is a very handsome plant, with larger flowers

LILIUM HYACINTHINUM WITH ITS DANGLING BELLS.

which make up in size and form what they lack in variety of colour, for although there is a white variety, the rest are all one pleasing shade of blue.

The Portuguese are said to make use of the flower heads of scabious for funeral wreaths, under the name of Saudade.—EDWARD CAHEN.

PERENNIAL LARKSPURS.

THE great value and beauty of delphiniums as occupants of the herbaceous border are well known and there is no need to dwell on their uses or effectiveness in this section of the garden, but there are many other places where delphiniums should play a much greater part. In isolated groups, in long borders, on the outskirts of the shrubbery, or in informal groups on slightly rising ground almost no other herbaceous plant is capable of producing such a brilliant display of colour.

The delphinium of to-day cannot be classed with the perennial larkspur of yesterday. The improvement during recent years is remarkable; a wider and finer range of colour, a superiority in size and shape of the "pip," and a greater variation in height all tend to increase the uses of this plant, besides adding to its beauty.

Delphinium planting time will soon be upon us, and one must consider not only the position in which to plant but the question of colour grouping also. As a general rule, bold groups of one colour produce the best effect, and each variety should be confined to a separate spot—the paler and more delicate tints are then not killed by the richer tones. The white-centred varieties of gentian blue should not be in close association with the semi-doubles of mauve and purple. Rosy purple against clear blue strikes an incongruous note, but two tones of the same colour blend well together.

Modern lists of delphinium varieties are long and contain many choice colours; a few of the best for general purposes are: Millicent Blackmore, Rev. E. Lascelles, The Alake, Moerheimi, King of Delphiniums, Norah Ferguson, Harry Smetham, Sir Douglas Haig, W. T. Ware, Blue Bird, General Byng, Moonlight, Smoke of War, Robert Cox, Little Boy Blue, Mrs. Creighton, Elsa, Duke of Connaught, Lorna Doone, Lizzie Van Veen, and Mrs. Townley Parker.

Delphiniums prefer a rich soil, and to light soils cow manure should be added. In all but heavy soils, planting should be done soon. Where the soil is on the heavy side, it is far better to wait until the spring to plant, and at this time to attend to the improvement of the site, which can be achieved by deep trenching and addition of lime and grit.—M. P.

THREE INTERESTING LILIES.

THE following notes and illustrations of three of Farrer's lilies may prove of interest to readers of THE GARDEN:

LILIUM HYACINTHINUM (FARRER NO. 1064).

The flower is well shown in the illustration. It is of a soft smoky lilac colour, each petal tipped with vivid green. Flowering in June, it grows to a height of 4ft. 8ins. The bulb seems to perish after flowering just as that of L. giganteum. It remains to be seen whether offsets appear round the old bulb. Seed is freely produced and ripens well.

LILIUM BROWNII VAR. COLCHESTERI (FARRER NO. 911).

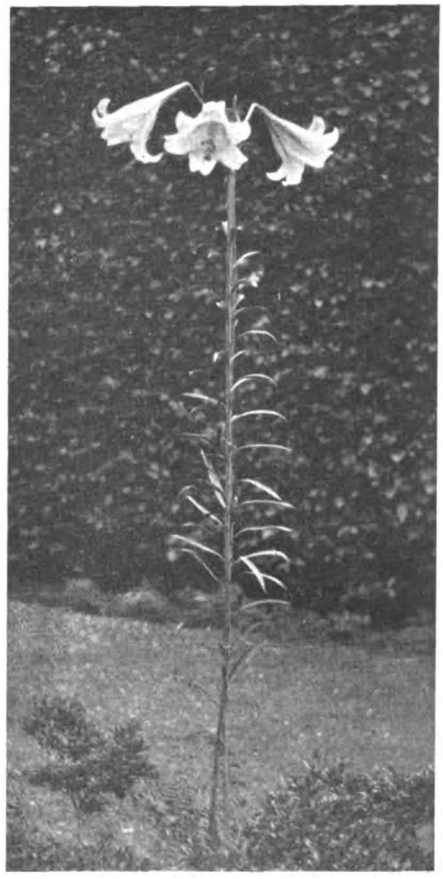
This is a plant raised from seed collected by Farrer in 1919, and is now in flower, 4ft. 8ins. in height, the flower 5ins. by 5½ins. across the petal, with a dark crimson line outside and a green stripe inside the flower.

LILIUM SPECIES (FARRER NO. 1122).

We have a very fine form of a species flowering in July, yellow, with a deep maroon blotch in the centre of the flower. Many of the plants were 6ft. high, producing ten to twelve flowers.—K. MCDOUALL, *Stranraer*.

[Experts differ as to the exact specific name of this plant. Mr. E. H. Wilson in his "Lilies of Eastern Asia" calls it by

LILIUM NEPALENSE. F. 1122.



THE TALL AND HANDSOME LILIUM BROWNII VAR. COLCHESTERI.

Franchet's type name of L. ochraceum. Professor W. W. Smith, on the other hand, believes that Farrer 1122 is L. nepalense var. burmanicum, and that L. ochraceum is the Chinese representative of L. nepalense and is conspecific but varietally different. In which case nepalense would hold good, being the older name.—ED.]

ROSS'S WATER AVENS.

GEUM ROSSII, a scarce American species, is obtainable from hardy plant nurseries, and is worthy of the notice of those who purpose adding to their rock gardens or who think of obtaining new plants for the front of the border. It hails from North America, is perfectly hardy and is highly pleasing with its shining foliage and its good yellow flowers, on stems which vary from 3ins. to 9ins. high. It would be wrong to state that it has the free-flowering brilliance of G. Borisii, as it more nearly resembles the best forms of G. montanum, a shy bloomer in many places. G. Rossii does not always flower with the freedom we would desire, and I have recently formed the opinion that in the past it has frequently occupied too dry a situation and that it will give much more satisfaction in a moist position. It is said to be properly named Sieversia turbinata, but this name is not likely to be readily adopted, and it almost invariably figures under the easier one of Geum Rossii in lists and in gardens. Its shyness of flowering in many gardens is the great barrier to a plant which has such attractive foliage as this.—S. ARNOTT.

THE CULTIVATION OF THE CURRANT

NOW IS THE TIME TO THINK OF PREPARING NEW PLANTATIONS OF BUSH FRUIT.

THE black currant is perhaps more generally grown than any other fruit, and it is unusual to find even the smallest garden without at least a few bushes. It cannot, however, be claimed that they all yield good crops, and in many cases the bushes are almost useless.

At one time the culture of black currants was a fairly easy matter, and under good cultivation bushes were kept in healthy bearing for many years: fifteen to twenty years being quite common. Now, owing to the prevalence of the pest "big bud" or black currant mite, and the newer trouble of "reversion," the profitable age of the bushes has been curtailed considerably.

Bushes attacked by big bud are easily recognisable, for, as the description implies, the affected buds are swollen much above normal size. Such buds contain thousands of mites, which feed on the embryo leaves and render the buds abortive.

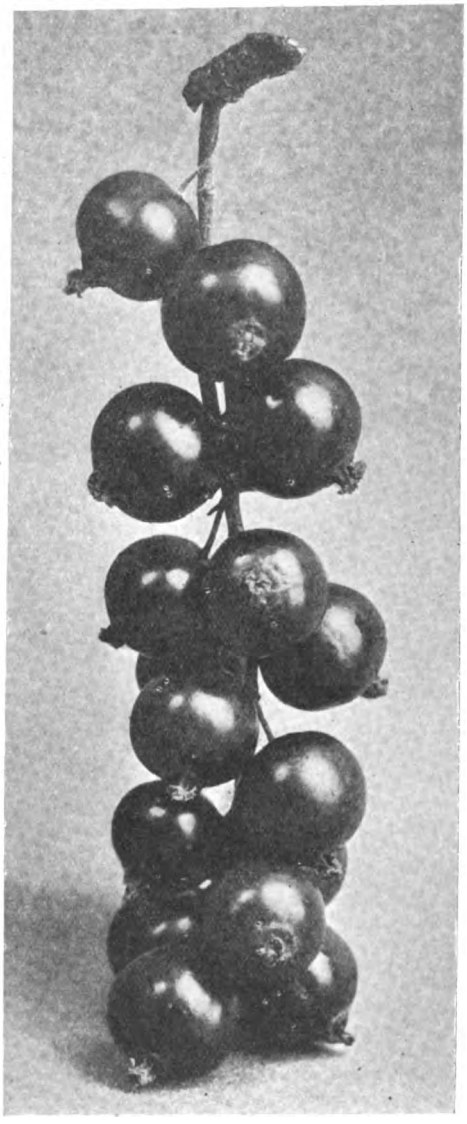
Control is, no doubt, the wisest measure. This comprises the propagation from clean stock, burning prunings and hand-picking. The latter, provided a start is made with clean stock, is most important. The bushes should be examined and as soon as any attacked buds are detected they should be picked off and burned. It is also advisable that the buds above and below the infected ones be removed, as they often contain mites. It is most important when buying to insist upon getting a healthy stock.

The next step is to plant, if possible, on a piece of clean ground. This will not, however, ensure immunity, especially if any infected bushes are growing in neighbouring gardens. In this case infection may take place as the mites migrate during March and April. Hence it is the duty of all to endeavour to keep the bushes clean. It is claimed for certain varieties that they are immune, or at least much more resistant than others. Black currants can be classified into groups according to the colour of their buds. Most varieties come under either (1) reddish buds or (2) whitish buds. It would appear that the varieties having the reddish buds are less subject to attack than the whitish ones. A few popular sorts under these characters are (1) French, Seabrook's Black and Boskoop Giant; and (2) Baldwin and Goliath. It is fairly generally known that the two latter varieties are particularly liable to attack; but all varieties can probably be found infected in one place or another.

CULTURE.

The black currant will thrive in any good garden soil, though a deep sandy loam is best. In any case it must be well drained. The ground should be double dug and, if necessary, plenty of farmyard manure incorporated at the time of digging. It is by no means easy to get exactly the manure one would like, but pig-manure is generally considered about the best, though any good farmyard manure will do.

To obtain the best flavour they should be planted in an open situation. They will, however, do quite well on borders facing north, and in such positions provide a succession of fruit to those planted



BLACKSMITH, A VARIETY OF GOOD QUALITY.

where they get the full benefit of the sun's rays.

In small gardens black currants and gooseberries are often found bordering walks. This is convenient for gathering, perhaps, but I prefer to see them given a space to themselves, or, where space permits, intercropped between top fruit.

PLANTING.

Planting is best done in autumn, but it can be done at any time from autumn till spring if the soil is in a suitable condition. At one time it was usual to plant the bushes 6ft. apart each way. Now, some growers adopt different methods, owing to the big bud and reversion trouble. One system is to plant 6ft. apart each way, but, instead of planting one bush at every 6ft., three are placed triangularly about 18ins. apart. The idea is to prodcure a good crop off the space within a few years and should the plants then show signs of reversion or have much big bud on them they are rooted out and the grower has the satisfaction of feeling that the space has not been wasted. Another system is to plant at 6ft. between the rows and 3ft. from plant to plant.

Holes sufficiently large to take the roots easily should be opened, and the roots exposed as little as possible before planting. Some fine soil should be well worked among the roots. This will ensure them getting a good start. Tread fairly firmly and finish neatly, leaving a loose surface.

When it is convenient to do so, one year old bushes should be chosen instead of two year old, which are generally planted. The first will receive less check at transplanting than the larger two year old bush.

When planting a yearling it is important to cut the growths hard back. During the second year, under favourable conditions, three good growths or more will be produced, and these will form the base of a good bush.

When buying two year old bushes, unless specially asked for, the number of growths may easily vary. Should any of them have only two growths one should be cut hard back. The subsequent pruning of such bushes is simple and merely consists of cutting out old wood after fruiting and encouraging young shoots from the base.

CULTIVATION AND MANURING.

The black currant is a gross feeder. Healthy bushes have masses of fibrous roots which are active practically all the year round. This fibrous root system should govern much of the work.

On no account should the soil around the trees be deeply dug. This would not only be likely seriously to check growth by damaging the roots, but it is generally believed that such treatment is conducive to reversion.

Weeds should be kept down by hoeing. Mulching is an important item, especially when the bushes get into good bearing. A splendid dressing is that from old hot-beds. These are generally made up of stable litter and leaves, and such a mixture would maintain a fine mulch into which the fibrous roots would penetrate. Top-dressings of farmyard manure are required annually. These can be given after pruning. A combination of farmyard manure and artificials is better than either separately.

A moderate dressing of farmyard manure would be such as to give a thin covering around the bush to the extent of its spread. This could be supplemented in spring by 4 oz. superphosphate, 2 oz. sulphate of potash, and 1 oz. of sulphate of ammonia to each bush. Bone-meal is a good fertiliser, so also is fish manure given at the rate of 4 oz. to each bush in two dressings, autumn and spring. These manurings and mulchings will

Digitized by Google

play the dual part of feeding and conserving moisture. In most seasons this would be sufficient.

VARIETIES.

A few of the best varieties are: Baldwin, French, Boskoop Giant, Seabrook's Black, and Goliath.

BALDWIN makes rather a dwarf bush with compact growth. The fruit and trusses are of medium size, but are produced in greater quantity than some varieties with larger fruit and it generally returns the heaviest crop of those mentioned.

FRENCH makes a large compact bush. It is later coming into leaf and flower than most varieties, and for this reason often escapes frosts which some of the earlier varieties catch. The berries are of medium size, but it is a good cropper.

SEABROOK'S BLACK is a good variety and largely grown, and is claimed to be largely resistant to big bud.

BOSKOOP GIANT is a very popular variety. It is a strong grower and makes a spreading bush. The bunches of fruit are longer than any other and the berries are very large; but as the trusses are often produced singly from a spur, it does not yield such a heavy crop as some of the other varieties.

GOLIATH makes a medium erect bush with strong growth. The fruits are medium to large.

BLACKSMITH and EDINA are also grown in quantity, and are good sorts.

RED AND WHITE CURRANTS.

These are, fortunately, less troubled with pests than the blacks, and they escape both big bud and reversion.

The culture is, in many respects, the same as for the blacks. One important difference is in the method of training and pruning. They adapt themselves readily for training as cordons, fans or bushes. A good bush of red currant should have about eight to ten cordon-like branches. The fruit is produced on spurs. Each leader is pruned back during winter, allowing about 6ins. or 8ins. of new wood for extension until the full size is reached. The laterals are shortened back during summer to within a few inches from the main stem, and any superfluous ones removed entirely. This will admit light and air and assist in the development of fruit buds for the following year. At winter pruning the laterals or spurs are further pruned back to about 1in.

Red currants are often badly attacked by aphis, and this must be controlled. As much of this occurs on the tops of leading shoots, a few inches can be pinched off without injury and burnt, thus getting rid of a lot of the pest. In addition, dipping or spraying, as advised for blacks, is often necessary.

VARIETIES.

Three of the very best varieties are Laxton's Perfection, Comet, and Fay's Prolific. White currants are not much grown, but a few are generally appreciated. White Versaillaise is a splendid variety.

BERKSHIRE.

PLANNING AND PLANTING A FRUIT AND KITCHEN GARDEN

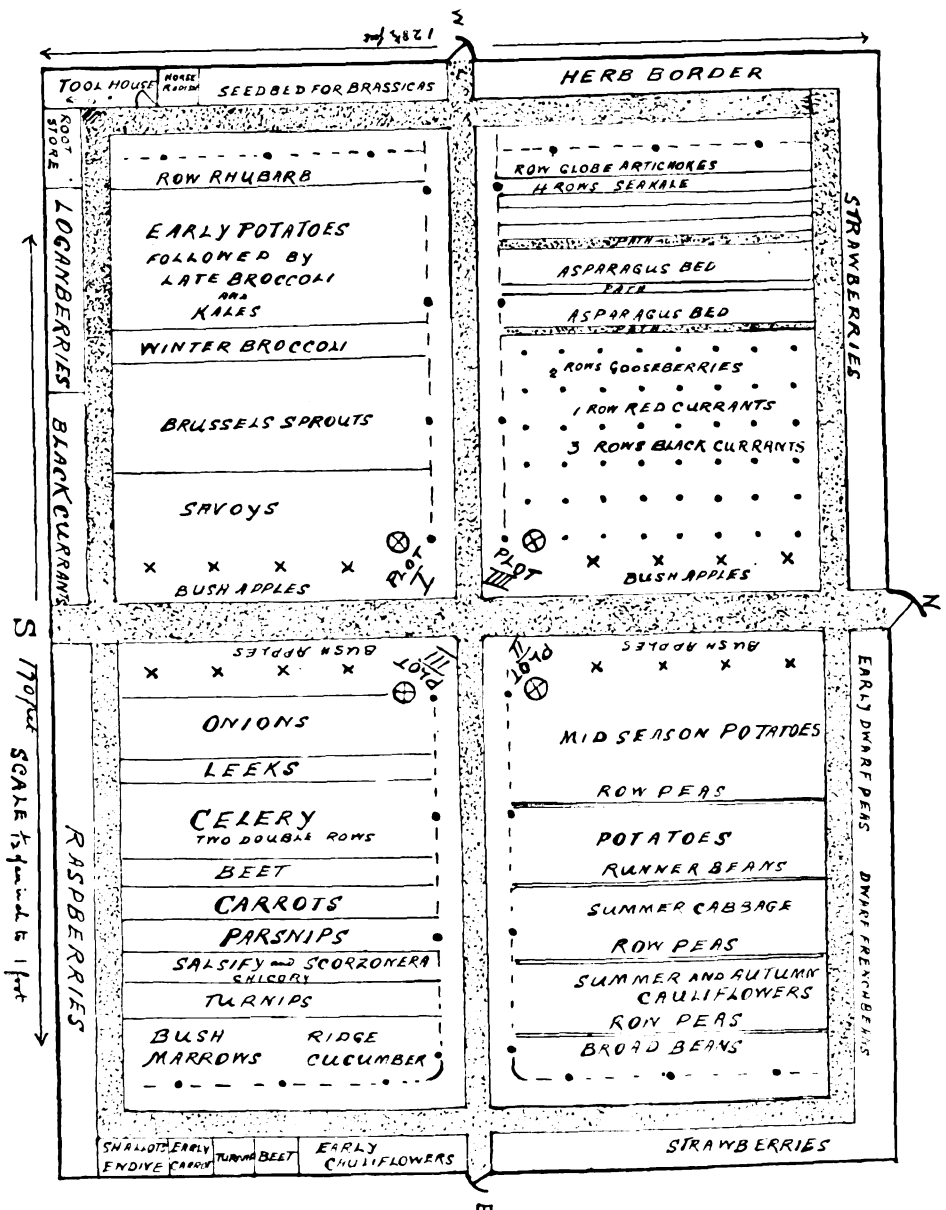
THE accompanying plan for a fruit and vegetable garden encloses an area of half an acre. Many modern gardens will not, probably, be surrounded by fine walls as was usual at one time. It is, therefore, to be imagined, in this case, that the garden is enclosed by a wooden fence or paling 6ft. high, such as is often seen at the present time.

On such fences cordon fruit trees of many kinds can be successfully grown, and a few low-trained fan-shaped trees would also be possible. On the south fence of 164ft. a few trees of peaches, nectarines and plums of the latter shape could be planted at 15ft. apart. Suitable varieties could be chosen from Hale's Early, Amsden's June, Goshawk, Barrington and Bellegarde (peaches); Early Rivers, Elruge and Lord Napier (nectarines); and Early Transparent Gage, Denniston's Superb, Jefferson's, Oullin's Golden Gage, Coe's Violet and Allgrove's Superb (plums).

The west fence would be ideal for cordon pears. These could be planted obliquely towards the south at 2ft. apart, and as 124ft. of space is available, a good collection of varieties could be accommodated. A few indispensable varieties are: Clapp's Favourite, Williams' Bon Chrétien, Souvenir de Congrès, Marguerite Marillat, Beurré Hardy, Beurré Superfin, Louise Bonne of Jersey, Doyenne du Comice, Josephine de Malines, ripening in the order named.

On the east fence, plums and sweet cherries could be grown as cordons or low fan-trained trees. A few reliable varieties are Czar, Early Prolific, Belle de Louvain, Pond's Seedling, Monarch and President (plums); Early Rivers, Frogmore Bigarreau, Governor Wood and Elton Bigarreau (cherries).

Loganberries, raspberries and black currants are suggested for the north border. The only fence space available would be behind the black currants, and this would accommodate two Morello cherries if desired.



Digitized by Google

Espalier-trained trees are arranged for on either side of the long central walk and set back 4ft. from the edge, 18ft. being allowed between each tree. The space allows for sixteen trees, and the following varieties of dessert apples are suggested to give a succession: Irish Peach, James Grieve, St. Everard, Ellison's Orange, The Houblon, Cox's Orange Pippin, Mannington Pearmain and Sturmer Pippin.

Culinary sorts should be chosen for the eighteen bush trees on either side of the central cross walk. A few excellent and popular sorts are Potts' Seedling, Early Victoria, Rev. W. Wilks, Stirling Castle, The Queen, Lane's Prince Albert, Bramley's Seedling, Newton Wonder and Annie Elizabeth.

In the four circles set at 16ft. from the centre of cross walks, standard apple trees are suggested. Coronation, Cox's Orange Pippin, Chas. Ross and Allington are a few good ones.

At each end of the garden, space is allowed for six espalier-trained pear trees. Conference, Pitmaston Duchess, Emile d'Heyst and Conseiller de la Cour can be recommended as likely varieties to give satisfaction.

A black currant bush could be planted between each of the bush apple trees, which are 10ft. apart. Space is also given to this popular fruit on Plot 4 and on the north border. Owing to the normal profitable period of black currant bushes being often curtailed through an attack of big bud mite, unorthodox systems of planting are occasionally found, such as planting in groups of three at 1ft. apart ***: the object being to obtain value for space while the trees are young and vigorous. This system might be tried on the north border, where the area would accommodate six groups through the centre at 6ft. apart. On Plot 4 single bushes should be planted at 6ft. apart. Popular varieties are Boskoop Giant, Baldwin, Seabrook's Black and Edina.

One row only is allowed for red currants, as this fruit is not in great demand. Fay's Prolific and Laxton's Perfection are two of the best sorts.

Choice gooseberries are Langley Gage, Langley Beauty, Whinham's Industry, Warrington, Green Gascoyne and Lancer.

Strawberries are placed on the south and west borders; these and the north and east are 6ft. wide. The two positions give a total length of 144ft. and would take rather over 200 plants. Three plants should be set at 18ins. apart across the border with 2ft. between the rows.

VEGETABLES.

An examination of the plan from the vegetable standpoint will show that consideration has been given to the rotation of crops, continuity of supply, and variety.

Plot 1 is mainly for brassicas.

Plot 2, potatoes, peas and beans, with an intercrop.

Plot 3, roots.

Plot 4, permanent crops.

This allows for a three years' rotation course. Thus, brassicas would in the three years occupy Plots 1, 3, 2; potatoes, etc., Plots 2, 1, 3; roots, 3, 2, 1.

Each year, after clearing the root crop, the ground should be double dug and fairly well manured for the following year's brassica crop. The spring cabbage crop is frequently given a portion of the ground cleared of onions, and would reduce the space for double digging.

The brassica ground would be dug as the crop was cleared, and moderately manured ready for potatoes, etc.; artificial manures would also be given at the proper time. Following potatoes and other crops, the ground would be dug for root crops, no manure being given. Celery trenches would, of course, receive the necessary quantity.

The measurement of each of the four plots enclosed within walks is 72ft. by 52ft., or about 13 poles.

PLOT 1.—Twelve rows of early potatoes at 20ins. apart. Immediately these are dug the ground should be filled with broccoli and kale. Varieties must be carefully chosen in order of maturity. Veitch's Protecting, Snow's Winter, Eastertide, Late Queen and Whitsuntide should succeed each other; the largest proportion should be of Eastertide, as choice vegetables are generally scarce in early April.

Seven rows of Brussels sprouts will occupy the 18ft. allotted, and eight rows of savoys complete the plot. Best of All, New Year and Ormskirk Late Green savoys will provide a succession.

PLOT 2.—Ten rows of mid-season potatoes at 30ins. apart, one row runner beans, three rows of main-crop peas sown in succession. The spaces between the beans and peas are 12ft. each. One will take five rows of summer cabbage such as All Heart and Sugar Loaf, and the other five rows of cauliflower, White Queen and Autumn Giant.

PLOT 3.—Ten rows of onions will occupy 10ft.; double row of leeks, 3ft.; two double rows of celery, 12ft. On the ridges could be planted either early dwarf peas, dwarf beans or lettuce. Four rows of beet, 4ft. Five rows of carrots, 5ft. Three rows of parsnips, 5ft. One each of salsafy, scorzonera and chicory, 4ft. Five rows of turnips, in two sowings, 5ft. Bush vegetable marrows and ridge cucumbers complete the plot.

PLOT 4.—Permanent crops, with the possible exception of part of the seakale, which could be lifted for forcing and thongs replanted in spring. The two asparagus beds are 5ft. wide.

BORDERS.

Early dwarf peas in two or three sowings and dwarf French beans for earliest supply are given one of the south borders.

Following the peas, a portion could be sown with dwarf French beans for the latest crop, also spinach, etc.

The west border will be an ideal place for early cauliflowers, twelve rows (autumn sown) and planted in spring, beetroot, early carrots, turnips, shallots and endive, followed by lettuce, autumn-sown onions, winter spinach and the spring cabbage seed bed.

The north border in front and among currants might prove a congenial position for summer lettuce, especially if the weather be hot and dry.

The east border to left of outlet is chosen for the brassica seed bed and horse-radish. If a tool-shed is necessary inside the garden, as it generally is, the bottom corner of this border is the best place.

The border to right of door is an ideal one for a well planned herb border. Popular kinds, such as mint, sage, thyme, lemon thyme, tarragon, marjoram, chives, chervil and parsley should be grown in such quantities as will meet the requirements of the cook.

The narrow borders on either side of the central path will be especially useful for pricking out seedling plants, sowing small batches of seeds and for propagating purposes. A few garden frames will be a necessary equipment to a garden of this size, but whether they are placed inside the garden or in a frame yard is a matter solely dependent on individual circumstances.

The long central walk and the surrounding walks are 4ft. wide, and the cross central walk 6ft. wide.

ARTHUR J. COBB.

GARDEN TECHNIQUE

Notes on the Technical Side of the Garden and the Cultivation of Plants.

THE AUTUMN TREATMENT OF SOILS.

THE thorough cultivation of the soil at this time of the year is a task which, although somewhat arduous, must be regarded as one of the most essential factors towards successful cropping during the ensuing season. The abundant application of manures is of little avail without the correct working of the land. Too much emphasis cannot be laid upon the value of good deep cultivation at the latter end of the year, in conjunction with continuous surface cultivation during the actual growing periods. It is not sufficient simply to turn over the top spit with a fork and leave it. Wherever possible double digging should be resorted to in order that the sub-soil may be thoroughly broken up and aerated, while the top spit should be laid up in parallel ridges and left to lie fallow throughout the winter. The nutriment in the sub-soil is thus rendered more accessible to plant roots and the greatest possible area of the surface soil is exposed to the rigours of winter frosts. In this respect a spell of good hard frosty weather must be looked upon as a great boon to the cultivator, for it undoubtedly plays a great part in sweetening the soil and ridding it of many unwanted pests. If the soil is devoid of humus or has become impoverished from constant use, an application of stable manure is advised and this should be well mixed with the sub-soil when it is being broken up. If stable manure is not obtainable a dressing of Wakeley's Hop Manure will be found to give excellent results, supplying the soil with both humus and valuable plant foods. Where an abundant supply of garden refuse has been collected, this should be treated with "Adco," which is a proprietary compound recently introduced. By this method a quantity of really

ANTHONY WATERER
(Deceased),
Knap Hill Nursery.

Mr. P. H. Martineau and the Public Trustee (the Executors of the Will of the late Mr. Anthony Waterer) have agreed that, as from the 5th October, 1925, the business, which was formerly carried on by the late Mr. Anthony Waterer, and since his death, by his Executors, shall be carried on by Mr. Hosea Waterer.

Mr. Hosea Waterer proposes to carry on the business under the name of Knap Hill Nursery (late Anthony Waterer) Proprietor, Hosea Waterer, and cheques should be made payable to "Hosea Waterer."

Yours faithfully,

(sd.) MARTINEAU & REID,

Solicitors to the said Executors.

good synthetic manure is always on hand which is rich in humus and nutritious plant foods. Liberal applications of lime are usually advocated at this period, but care should be used in this respect. Copious dressings with this material are unnecessary where a sufficient quantity of free lime is present in the soil.—C. J.

ON CHERRIES.

THE cherry is undoubtedly one of our most popular fruits, and rightly so. It is practically the first of the season's fruits to ripen and for this reason alone is worthy of a place in every fruit garden. It thrives in a rather rich and sandy soil, to which a moderate amount of old mortar rubble or well slaked lime has been added. Broadly speaking cherries may be divided into two distinct types, the sweet or dessert cherry, and the Morello or pie cherry. If grown as standards, pyramids or bushes, they should be given an open, sunny position, but they are particularly valuable for training as wall trees. The earlier types of dessert fruit will be found to thrive on a south or west wall, while the Morello does exceptionally well on a north wall. They are best left unpruned the first year of planting and the less they are cut the better at all times, for they have a nasty habit of "gumming." The two types differ in this respect. The sweet cherry bears its fruit on spurs which form on wood of the previous year's growth and continue productive for a number of years, while the Morello type bears its fruit on the young, wand-like shoots that were formed during the last year's production. This is an important factor when pruning has to be considered. In dealing with the former, practically all side shoots must be kept in check and if the spurs come too thickly, they should also be thinned. In pruning the latter type, however, we must be careful to retain as much as possible of the new growth to take the place of old wood that should be cut away after the fruit has been gathered. Good varieties of dessert cherry are Early Rivers (June), Black Tartarian (June), Black Heart (July), Bigarreau (July), Noble (August), Florence (August). Good cooking varieties are Flemish Red (July), Kentish Red (July), Morello (August).—J. C. A.

SOWING BROAD BEANS AND PEAS.

THE broad bean thrives in a retentive soil where the latter is well prepared; the pea does best in a lighter medium. In nine out of ten gardens it is possible to sow seeds of these two valuable vegetables in the autumn with a good prospect of success. Where soils are quite unsuitable, it is much the wisest plan to defer sowing until the spring, either under glass or in the open border, and to devote the time and energy to improving the soil in the meantime. In the spring we naturally select an open border for our first broad bean crop; but in the autumn we, as naturally, select the warmest for both beans and peas. An early maturing variety, too, should be sown. First, the soil should be trenched or, at least, deeply dug and the manure buried. I use the word "buried," as it is advisable to do this so that the roots of the plants will not come into contact with the manure before next spring. It should, therefore, be at least 5ins. below the seeds when the latter are sown, and not in a solid mass, but well mixed with the soil. The young plants only need the support that the unmanured portion of the soil can afford them from the time of germination till early springtime, when growth becomes active. When the roots reach the manure the plants become strengthened to flower and pod well. A forced, soft stem and flabby leaves will not ensure such satisfactory crops. Use red lead against attacks by birds, mice and rats.—G. G.

PLANTING FRUIT TREES NEAR WALLS

CULTIVATORS who possess suitable walls, whether they are ordinary garden walls or those of farm or house or shed buildings, should make the most of them for fruit growing. Full use is not made of good available walls in this country, and I think it is a great pity that they remain so bare. I am not advocating the nailing of branches to walls, as nailing does much damage to them and makes holes wherein insect pests hide. Close-to-wall wires are much the best. Then we have the foundations of walls to consider. From a cultural point of view it is not advisable to plant fruit trees with their roots and main stems close to the wall itself, so that the foundations of the latter will not be disturbed. The holes for the roots should be made large enough to contain them without any cramping, and when the roots are placed all of them should be spread out from the wall, not any towards it, the stem of the tree being at least 9ins. from the face of the wall; this distance allows for the free swelling of the stem without its coming into contact with the wall much later on. Nearly all wall trees suffer through lack of water at some time during the year, so that, on sloping ground especially, level surfaces quite 3ft. by 2ft. should be the rule, to retain both rain-water and that applied through a watering-can for the benefit of the roots. It always pays the cultivator to take some trouble in getting good fibrous loam for every tree and old mortar rubble for stone fruits.—HANTS.

CORRESPONDENCE

CYCLAMEN.

SIR,—Your correspondent in the article on the above (October 3rd, page 553) has omitted one of the best of hardy cyclamen, C. Atkinsii, the hybrid between C. ibericum and C. Coum. There are two or three different forms listed now. They flower like the parents at a season when flowers are scarce and on this account are doubly welcome. Once established they flower with remarkable freedom and in a sheltered spot seem to be able to withstand a lot of rough weather.—KUKLOS.

SUPPORTING MICHAELMAS DAISIES.

SIR,—For some years past I have practised the single stem method of growing these beautiful plants, but as the Rev. Joseph Jacob remarks, the side shoots are brittle and are frequently broken off in inclement weather. To overcome this I stake each plant separately, using an iron rod, when the side shoots have fairly well developed. I find that a loose tie of raffia around all is sufficient to support the side shoots; this has proved quite satisfactory and if it is done in good time no support or tie of any kind should be visible and the plants will maintain their natural and graceful shape.—A. WHITEHEAD.

RANUNCULUS GLACIALIS IN THE DOLOMITES.

SIR,—I was interested to see in THE GARDEN (Oct. 24th, page 598) a picture of Ranunculus glacialis taken from the Piz Langard. I have never visited Switzerland in the summer, but I have met Ranunculus glacialis often in the volcanic outcrops of the Dolomites. There is one particular area where it grows in the most princely abundance and in a wonderfully fine broad-petalled form—the last few hundred feet of the climb to the Passo di Selle. There the form is huge,

THE BEAUTIFUL SPREADING R. PARNASSIFOLIUS.

and the colour varies, according to the age of the flowers, from pure white to deep rose. I was most impressed by the intermediate colours of lovely apple blossom tint. I have seen the plant flower in cultivation, though it is exacting and seems to want a mixture of heavy non-calcareous clay and abundance of stones, but the blossoms never seem to become pink in England. I might claim, I think with some reason, that this few acres of ground at the summit of the Selle pass, at about 8,000ft., provide a richer provender for the flower lover than even the appetising description of the summit of the Piz Langard. There were there Ranunculus glacialis, Geum reptans, Eritrichium nanum, Ranunculus Seguieri, R. parnassifolius (there is limestone on the pass as well as granite), Primula glutinosa, P. minima, Anemone baldensis, Gentiana brachyphylla and, I believe, G. imbricata. Farrer speaks encouragingly of hybrids between the two primulas, but in August, when I saw this paradise, only glutinosa was in flower.

I enclose a photograph which shows that rare but hearty high alpine Ranunculus parnassifolius in its fine and most spreading form, a plant that will do the same for you at home if you give it some limy soil and full sun and moisture.

And now, finally, with regard to Androsace glacialis in the Dolomites. Mr. Todd in his interesting talk about colour forms of alpine plants said that Androsace glacialis was invariably white in the Dolomites. I thought so myself until my last visit. I had found it invariably white on the granites round the Pordo Joch. But this last time I found a new volcanic outcrop—on the Coutrin Joch, where the southern face of Marmolata drops to earth—a comparatively tiny strip surrounded by white limestone. There I found two or three pieces of pink as well as white Androsace glacialis. But whether it was as pink as the plant found in Switzerland I do not know, because I have never seen the Swiss plant except at

Digitized by Google

Mr. Clarence Elliot's nursery, where I am sure he will forgive me when I say there were only one or two flowers! Happy are those who can produce even those!—R. L. HOLDSWORTH.

PLANTING THE IRIS.

SIR,—There is much question about the best time to plant the iris. Some say July, some August, others October. Let those who like value for money plant in July. I bought a novelty at a high price and planted it in July. It was a single plant. By October it has thrown up five new strong shoots each now 6ins. high. This increase has more than paid the cost of the plant. If I had planted in October, the single plant would have remained a single plant well into the middle of next year, as no nurseryman would be so good as to supply me with a novelty with all this new growth attached to it.—H. C.

CROCUS PULCHELLUS.

SIR,—I cannot answer Mr. Blanchard's question about his interesting specimen of Crocus pulchellus specifically, as I do not remember actually to have seen the particular abnormality enquired about in that particular species. I think, however, that Mr. Blanchard will find such increases or reductions in the number of segments not uncommon among crocus species generally. I have found them in a good many species. So large a number of segments as ten is, of course, not very common, though I have actually seen in a specimen of C. chrysanthus fuscotinctus many more.—H. A. GREATOREX.

SARCOCOCCA RUSCIFOLIA.

SIR,—I see Mr. Canning-Wright mentions this plant in his article on "Fragrant Shrubs," in THE GARDEN of October 24th, 1925. We have grown it here for years and this year to add to its beauty, it is carrying a large crop of red berries. This is the first time it has fruited with us. It is a shrub of easy culture, thriving equally well in shade or sun, and no doubt will be more frequently met with when better known.—R. MOORE, *Thorpe Hall Gardens, Essex.*

GARDEN RUBBISH.

SIR,—With reference to Mr. Macself's article on the use of garden rubbish as manure in your issue of October 3rd, I consider that he greatly exaggerates the dangers likely to arise therefrom.

I know nothing about "Adco," as I have not yet used it, but I should say there is certainly a future for some agent which will add to decayed vegetation the constituents which are lacking, so as to form a balanced plant food.

I have trenched in all soft garden rubbish, such as cabbage stalks, dead leaves, mown grass, etc., in these gardens for the past eighteen years, and have never experienced any increase of pests through doing so. In fact, my difficulties with pests have gradually become less, owing to improved methods of controlling these by spraying, etc.

The only refuse we burn is hard, woody stuff, which does not readily decay, and of this we build a tidy and shapely heap. This latter is lit on a favourable day, and is generally all consumed in an hour or so, the resultant ashes being used in the garden also.

By following this method I have quite done away with the unsightly and smelly rubbish heap, and also the equally objectionable smother fire, both of which become a nuisance when hard and soft rubbish are carried to the one heap, and futile efforts occasionally made to burn it.

If all the dangers depicted by Mr. Macself really exist, generations of gardeners must have been mistaken in regarding leaf-mould as one of the safest and most reliable constituents of nearly all their composts. Because, although we are certainly advised to use only clean beech and oak leaves for the making of this, I do not suppose it would be possible to find a bushel of dead leaves of any kind, which, under the microscope, would not display thousands of potentially harmful eggs and spores. It is a point of some importance to all gardners—T. E. TOMALIN.

THE IMPERIAL FRUIT SHOW

THE Holland Park Rink, London, which was quite recently the venue of the Royal Horticultural Society's great Autumn Flower Show, has presented us with an entirely different appearance during the last ten days from October 30th until November 7th, on the occasion of the annual Imperial Fruit Show. In place of groups and banks of glowing foliage and beautiful flowers, the centre of the hall was occupied with stands which simulated glorified open shops where the various firms and associations displayed their specialities with great artistry.

It is a pleasant thing to be able to record that from the artistic point of view as well as in usefulness the honours lay with the English nurseryman. We missed the usual exhibits of a few traders—Messrs. George Bunyard and Co., for example—but many others were splendidly represented. At one end of the hall Messrs. Waterer, Sons and Crisp had little bush apples heavily laden with magnificent fruits, and fronted with innumerable baskets of brilliant apples and luscious pears.

Other growers set out their spaces with model plantations of perfectly grown fruit trees.

Messrs. W. Seabrook and Sons had two spaces where they planted apples and pears over currants of all types, and had ideal fan-shapad trees growing against their building. The cordon apples of Messrs. Daniels Brothers claimed the first attention of the fruit grower. Their specimens were fully 5ft. long and ideally studded with fruiting spurs. The chief varieties were Cox's Orange Pippin, Ellison's Orange, Worcester Pearmain and King of the Pippins. On a stand in the front of their exhibit they had magnificent bunches of Muscat of Alexandria and Gros Colmar grapes, with many baskets of apples and pears of equally high quality.

Their new dessert apple Lord Lambourne, which is in season from October to December, was prominently shown by Messrs. Laxton Brothers, whose older varieties included Houblon, Bedford Pippin, Roseberry and Worcester Pearmain of glorious colour.

In a very attractive stand the Barnham Nurseries Company had perfect little fruit trees and handsome fruits of Washington Nonpariel, Bismarck and Worcester Pearmain. A useful plantation of apples, pears and black currants was set out by Messrs. Brinkman Brothers.

Recognising the fact that any association content to go on in the same old way year after year soon loses hold and interest, the promoters of the Imperial Fruit Show have wisely formulated a progressive policy and have a number of new features this year. These mostly appeal to the exhibitors and render it possible for every grower in the kingdom, no matter on how small a scale, to exhibit. With this end in view the number of packages of fruits has been materially reduced.

As might have been expected, apples largely predominated at the Show, and with the more important classes these were packed in boxes. In nearly every instance great skill and judgment had been displayed, and this method was equally as successfully practised by the home grower as by the Colonial. Success in packing boxes of apples requires great judgment in grading, and this our home growers have acquired in a marked degree, and there was such perfect alignment of the fruits that it almost seemed as though the fruits were grown for the boxes rather than the boxes made for the apples.

In certain quarters there is a general impression that Colonial-grown apples are invariably more highly coloured than English fruits, but a visit to the Show would do much to correct this. At first sight it may seem that the fruits of Jonathan, Spy, King, Snow and Spitzbergen, to name the chief Colonial highly coloured apples, were better in this respect but the critical visitor soon realised that this superiority was more apparent than real and owed the impression to sheer quantity, for in the English exhibits, and especially those from Kent, the colour of Cox's Orange Pippin, Houblon, King of the Pippins and Charles Ross, to name only a few, was fully as brilliant as the Colonial samples, and in addition these fruits also possessed the extra merit of an underlying flush of golden colour, which invariably tells of high quality. Nothing in the apple line could be more attractive or appetising than the scarlet and golden King of the Pippins in many of the United Kingdom exhibits.

The chemical aids to successful fruit growing received due recognition at this great Show and various firms were prominently placed. For example, the well known Abol hand and knapsack sprayers with samples of their chemical manures and specifics were attractively displayed. Nicotex, No. 2 Fruit Wash and Katakilla, prepared by McDougalls, were set out with fruits grown by their aid, as also were Messrs. Bugges' insecticides.

Fison's fertilisers have long been valued, and the display was admirable; while Alvesco, which Messrs. Murphy and Co. recommend for the extermination of the white fly pest, was also on view.

Messrs. G. H. Richards, Limited, claimed that theirs was the only exhibit of horticultural sundries, and on a large stand they set out every aid and necessity that could be imagined, while giving special place to their XL All fumigant.

The great importance of the scientist in relation to cultivation was fully displayed. The Ministry of Agriculture had a selection of leaflets relating to fruit and the fruit-growers' enemies. From the East Malling Research Station were sent illustrations and diagrams, while the authorities from Long Ashton showed the result of studies in the development of the Royal Sovereign strawberry and the relation between the stock and the scion in the growth of fruit trees; and the University of Bristol set out samples of the chief cider apples and much information on cider making.

In association with these exhibits representatives were eager to discuss the grower's problems and to offer up-to-date suggestions, while a full programme of lectures by eminent authorities and demonstrations on pruning fruit trees were carried out.

LORD LAMBOURNE

President of the Royal Horticultural Society.

WE have received the following letter from Sir William Lawrence, Treasurer of the Royal Horticultural Society, and we have much pleasure in bringing it to the notice of our readers :

" SIR,—Lord Lambourne, the President of the Royal Horticultural Society, has, with characteristic *bonhomie*, acceded to the unanimous wish of his colleagues on the Council of the Society and consented to have his portrait painted. Mr. Wilfrid de Glehn, A.R.A., has been commissioned to paint the picture, which will hang in the great new hall which the Society is about to build in Westminster.

" Horticulture has never had a more devoted servant. In spite of the severest domestic bereavement and frequent ill-health, Lord Lambourne has with the greatest of courage continued to preside over the meetings of the Council and to guide its policy with mature judgment and sound commonsense ; the great and increasing success of the Society is largely due to his benevolent control.

" All lovers of gardening, whether amateurs, professionals or seedsmen, regard him with the same warm affection as do his innumerable friends in other walks of life, and I invite them one and all to unite in this commemoration and to send their subscriptions to the Chief Cashier, Royal Horticultural Society, Vincent Square, Westminster, S.W.1."

It seems that a few words regarding Lord Lambourne and his career will not come amiss at this time. As President of the Royal Horticultural Society since 1919, in which year he succeeded Lord Grenfell, he has endeared himself to all the many members through his personal charm and courtliness, and his wide and deep knowledge of all horticultural problems. It can be truly said of him that he has been born and bred in horticulture, and what he does not know about the various branches of this wide subject is scarcely worth knowing. He has always taken a keen and active interest in all the particular lines of study associated with and composing the science of horticulture, and his own garden at Bishop's Hall, near Romford, stands as testimony to his energy and thoroughness. As President he has done much to further the interests of the Society in its various spheres, and the strong position in which the Society now finds itself is in no small measure due to his untiring efforts on its behalf. He carries the honours of the Society with great ease and charm, and the more arduous duties connected with his office he fulfils promptly and with commendable understanding. We all know him as a lover of flowers and of plants and all matters pertaining to their cultivation, and that to some extent gives a clue to the high and honourable position to which he has attained in the horticultural world. We hope that the appeal which is now being made by the Treasurer of the Society will meet with a generous response from from all Fellows wherever they may be situated, for probably no other President has deserved recognition more than Lord Lambourne, whom we trust has still many years of office before him.

LORD LAMBOURNE

SOME PLANT GROUPINGS

EVERY garden—every modern garden, at any rate—has its accidents, and these may be good or bad. They can be very bad when a peculiarly virulent form, or hybrid, of Geranium sanguineum has elected to surround with a constellation of aniline stars a very esteemed cherry-crimson variety of Potentilla nepalensis. Even more grievous is the tragedy that is now being enacted by a conflict between the trailing garlands of Tropæolum speciosum and the crimson pendants of Berberidopsis corallina. The former, being no respecter of persons, has even attacked the gentle Mitraria coccinea, but here the result is not quite so disastrous, since the mitre-flower hangs most of its soft orange-scarlet trumpets below its foliage, while the tropæolum flames like a beacon on its crown. Devoutly do we pray that the flame-flower may never envelop Pentstemon cordifolius, for that would be sheer anarchy.

On a dry, hot slope, largely occupied by encrusted saxifrages, raoulias, anthemis, achilleas and other grey-leaved things, the blue bells (of Scotland) which are most attractive in the garden in August, have become hybridised with some of the garden kinds and, springing freely from seed, do their part in converting what might have been a colourless place during the later season into a symphony in silver and pale blue.

With any of the dwarf ericas these bell-flowers, which, by the way, appear naturally in various shades of blue, are always admirable, and it was Farrer, I believe, who suggested growing them and Senecio abrotanifolius in combination. The result of such a planting as the latter has been so pleasing that one can safely proceed with "the mixture as before," but exercising rather more licence in regard to the colouring matter. A paler yellow (such as that of Anthemis tinctoria var. E. C. Buxton, for example) gives an even more charming effect with the harebell blue than the ragwort gold affords; and the same may be said of the purer, cleaner blues. Ceratostigma Willmottianum against the silver and soft chamois yellow of the silver-leaved Potentilla Vilmoriniana is a case in point. Or we may hark back to the days when Hypericum Coris and Lithospermum prostratum Heavenly Blue were flowering together, each doing its utmost to emphasise the charms of the other. Hypericum olympicum var. citrinum may be a somewhat bloodless creature when isolated, or among whites or other yellows; but let it be seen against a mass of Veronica chathamica and the transformation fills one with wonder.

DAPHNE CNEORUM IN PLEASANT ASSOCIATION WITH A FEW PLANTS OF LINUM NARBONENSE.

Perhaps one has a kind of innate regard for blues and yellows, because these colours are the component parts of the ancestral and prevailing green. Anyhow, I find myself returning to them and can never have enough of the large-flowered evening primrose (Œnothera biennis) against the lavender of Solanum crispum autumnale as seen in evening light. Clematis Lady Northcliffe in combination with the golden-leaved hop will give something of the same effect, and you will find this again in a forest of water forget-me-nots of an improved form which is contending for place and power with Mimulus luteus and choking a watercourse in the struggle. Or, taking the hint direct from nature, there is the enthralling loveliness of billows of golden gorse in an azure sea of the vernal squill; and, at the other end of the season, the rare beauty of the brassy yellow dwarf furze accompanied by the luminous sapphire of the marsh gentian.

A SUITABLE GROUPING OF HELICHRYSUM BELLIDIOIDES AND JASIONE MONTANA AS A COVER TO STONE STEPS.

A rough, rocky bank which is the home of many saxifrages of the Cotyledon and lingulata class has gradually become besprinkled with self-sown tufts of Erinus alpinus, and the effect of the latter, a haze of heather-purple beneath the tossing plumes of silvery white and crimson, is extremely lovely. A group of Montbretia rosea in a mixed border has at its back a colony of Cypella Herberti—shrimpy rose and golden buff—but the blend is rendered still more charming when Cypella platensis adds its exquisite pale Wedgwood blue.

Blue and white and a delicate interpolation of shell pink is vouchsafed along the muddy banks of a streamlet, where a large-flowered, short-stemmed form of the grass of Parnassus has for companion that entrancing little jewel, our native Campanula (Wahlenbergia) hederacea, and the clear

Digitized by Google

rose of Anagallis tenella, the bog pimpernel. Blue, pink and white are again in unity where a rambling mass of Polygonum vaccinifolium has for next-door neighbours some pale blue willow gentians and a clump of the pure white form. This is in an open part of the woodland, where another charming effect is afforded by a mossy stump crowned by Selaginella (Lycopodium) helvetica and Linnæa borealis. The St. Helena violet creeps around the base of the stump, cyclamens appear at their seasons, and during August there is a bold clump of Deinanthe cœrulea with its exquisite, anemone-like flowers, waxen of texture and the colour of Parma violets.

A once barren and always unsatisfactory bank of poor soil has been given over to Helichrysum trinerve and the large-flowered variety of Lysimachia nummularia, both of which showed signs of being willing to take possession of the ill favoured place, and the result is good at all times. Several large bushes of Daphne Cneorum which flop over a border coping on to the grass are gradually being companioned throughout their whole length by the strays from some plants of Linum narbonense hard by. The blue of the flax is not by any means an intrusion upon the beautiful pinky crimson of the daphne: in fact, the two colours help one another, and the tall and airy stems of the linum give a gentle shade to the shrubs below which is not undesirable. Some rather raw-looking steps in the more or less wild heath garden were only planted a year ago, with Erica cinerea coccinea, Hypericum Coris, Thymus Serpyllum coccinea var. majus, and some select kinds of self-heal (prunella). These, with the help of Jasione montana, Helichrysum bellidioides, some galiums and other pretty natives which have cropped up, are already almost clothed with as cheerful a mixture of purple and gold, crimson, blue and white as one could desire, the very informality, including the licence given to the wildings mentioned, tending to moderate any leaning towards a too garish effect.

For the last of these random jottings I may allude to the singular beauty of a steep retaining bank which was planted some years ago with Erica cinerea var. rosea and Rosa Wichuraiana. When the former is in bloom (from July onwards), the rose, which has threaded its way for 15–20ft. through the heath, tosses out of those cushions of rosy crimson at intervals its lovely trusses of fragrant white flowers. The charm of this dual occupation is irresistible. Moreover, the rose is as well adapted for dry, hot banks as the heath. Both are vigorous and so well able to take care of themselves that they may be left to their own sweet will for years and years and never be other than delightful. A. T. JOHNSON.

ON MICHAELMAS DAISIES—II

GOOD wine needs no bush. The Novi Belgii are mostly "good wine." The following are some of those I call especially good:

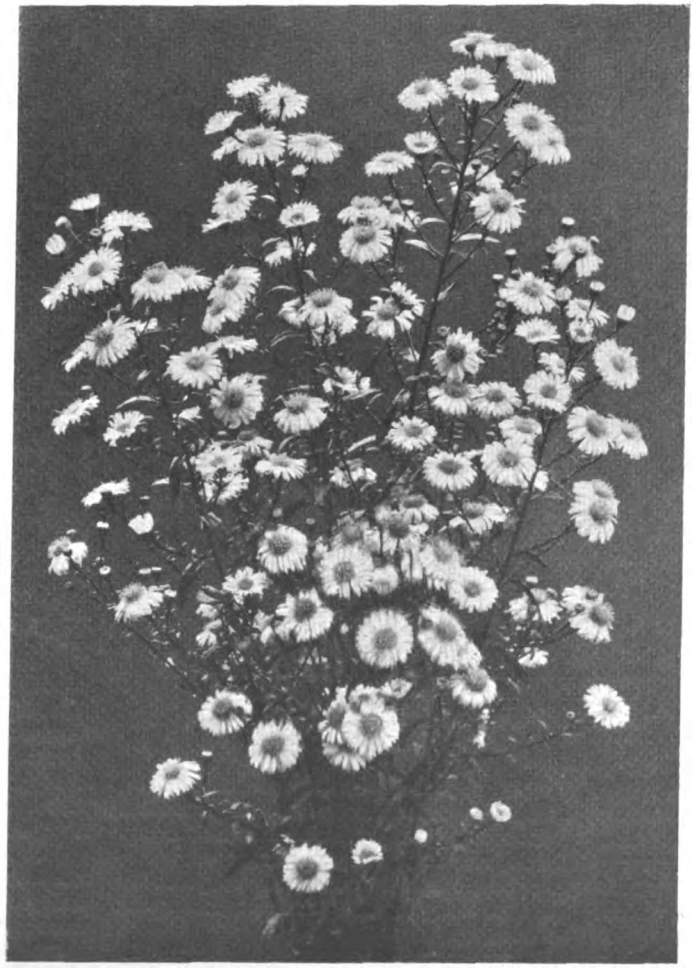
BLUE GEM.—No aster has impressed me this year as this has done. There seems to be more blue in it than in any other. And what a lovely shade! Soft, pale and alluring. I can describe my plants as 4ft. of height and 3ft. of bloom. What a laster, too! Hardly equal to Tennyson's "Brook," perhaps, but certainly of "Marathon" form. Its flowers are of medium size, and the happy mean between single blessedness and doubtful doubleness.

KING OF THE BELGIANS.—A tall one if you like. The very plant for the back of a border. The very large single flowers have several rows of orderly petals which do not encroach on the domain of the yellow centre, and which are of taking pale mauve colour distinctly suffused with pink. On the early side—Beckett's best?

BRUSSELS is something like the King, but not so tall, later to bloom and with a blue or lavender suffusion.

WALKDEN'S PINK.—A northerner, I believe. Introduced by Messrs. Dickson and Robinson of Manchester, who, as regards Michaelmas daisies, are the H. J. Jones of the north. Where is the pie into which they dip for their plums? Their catalogue contains a good many varieties not to be found elsewhere. Walkden's Pink is without doubt the most beautiful early rose, "They all love Walkden." It grows 4ft. high and is very free-flowering. Dome topped.

ALDENHAM PINK.—A late-flowering counterpart of the above, but a more intense rose. Mr. Beckett very kindly sent me in the spring one of his very latest roses to try. It is called Mermaid. The new-comer is no improvement in colour, but its individual flowers are a trifle larger. In my opinion Mermaid's special charm is its comparatively loose habit. We do not want all dome heads to our Novi Belgii. A certain number are all right, but enough is as good as a feast. The plants of loose habit, like Perry's Pink and Beckett's King of the Belgians, are usually preferred by visitors. I find I am getting into the old-fashioned way of naming. Nothing simpler has ever been invented. When schoolmaster Thomas Hogg wrote about florists' flowers in the early eighteen hundreds it did not matter how many Lord Nelsons there were. Barefield, Brown, Wood and Bates all had one, but I must own it was a little perplexing if it was not made clear if the name belonged to a scarlet bizarre or a scarlet flake.



ASTER PHYLLIS, OF FINE FEATHERY HABIT.

RED STAR, from Dickson and Robinson, is a singularly attractive plant, tall and of loose habit, and with deep rose flowers which are individually larger than most roses. It grows about 5ft. high. A fine novelty.

ELSA.—So beautiful that it almost reconciles me to doubles. I have seen it described as a "bright rosy lavender." I would rather say a soft lavender-rose. The rose colour is the dominant. The flowers are of good size and last well, changing from double to semi-double with age.

CATTLEYA is a smaller and paler edition of Elsa. It is not a bad thing and many visitors go for it; but, personally, I never can acclimatise myself to the want of a yellow centre.

MARGARET BALLARD.—Miss Peggy rightly put her foot down and said she must have a better thing than Peggy

Digitized by Google

Ballard named after her. I agreed with the lady. She has now got as her namesake a splendid double, deeper in colour than Elsa, equally as large, and quite its equal in every way. It has only just appeared in Mr. Ballard's list.

PHYLLIS.—All the varieties that I have seen which come from Mr. T. Bones are distinguished by their beautiful clear pale yellow centres. This trait appeals to me, for I cannot help feeling that a blurred centre does not look as well as a clean cut one. This same centre appears in his Perle Brilliant, which is much taller and carries its branches in a light separated way peculiar to itself. Both a pale helio. One special characteristic of Phyllis is its earliness. This and the rich lavender Lavender are the bell-wethers of the Novi-Belgii.

FREEDOM is a 1925 introduction and is a fine example of a tall-growing mid-season Michaelmas daisy. It has large clean-cut, deep rich helio blooms and a nice loose habit of growth.

QUEEN OF COLWALL.—I bracket this with King of the Belgians and Freedom as being three tall-growing mauve varieties which are very hard to beat. They are all mid-season and could be planted with every confidence to bloom at the same time. The Queen has those peculiar narrow ray petals with the ends all pointing one way as if the whole flower was being turned on a wheel, which are characteristic of many of Mr. Ballard's. It is rather a fair weather flower; heavy showers or long-continued fine rain give it a distressed and woebegone look. It is not, however, nearly as sensitive in this respect as Grey Lady. It is a great pity this last named suffers as it does in wet weather. It is a large taking flower of delightful opal grey colouring, but its long ray florets are its undoing. Hence when we plant it we must be prepared to take the risk of a wet autumn.

I think anyone getting any of the daisies named above will agree with me that one and all are well worth growing. JOSEPH JACOB.

A SELECTION OF HONEYSUCKLES

ONE or two species of the genus lonicera are to be seen in almost every garden, however tiny it may be, but the full value of the honeysuckles has not yet been realised by the majority of gardeners. There are at least one hundred species now in cultivation, many of which are eminently desirable plants either for the sake of their beautiful flowers, their delicious fragrance, their attractive berries or their neat evergreen habit. Most of them are very hardy and easily grown in any reasonably good soil. All are readily propagated by cuttings, layers or seed. The climbing species of the Periclymenum group are the most valuable garden plants, but a few of the shrubby species are very important also. The two winter-flowering honeysuckles (LL. fragrantissima and Standishii) belong to the latter group, and are indispensable plants where winter flowers are appreciated. L. nitida represents a totally distinct type of box-like evergreen, and is now being largely planted as a hedge plant, for which purpose it is well suited. Many of the shrubby honeysuckles introduced from China in recent years are not sufficiently showy to become useful garden plants, but the following selection consists of the finest members of the genus:

LONICERA CAPRIFOLIUM.—One of the first climbing species to flower and a very desirable honeysuckle. It is a strong grower and may be at once distinguished from L. Periclymenum varieties by the uppermost pairs of leaves being united at their bases. The young shoots are very liable to attack by aphides and require attention in early spring to avoid damage.

L. CILIOSA is a scarce but beautiful climber, bearing large clusters of rich yellow flowers. It blooms about June, and hails from north-western America.

L. DEFLEXICALYX is a handsome Chinese shrub, not very showy, but of very elegant habit and a good thing to plant by itself in rough grass where it has space to develop.

L. ETRUSCA, sometimes listed as L. gigantea superba, is one of the very best climbing plants that one could desire—at any rate, in the milder parts of the country. Being a native of the Mediterranean region, it is, naturally, less hardy than our native honeysuckle. It is a deciduous species, but produces its very downy young leaves so early in the year that it may almost be regarded as evergreen for gardening purposes. Once established, L. etrusca makes rapid headway, and soon covers an old apple tree or worthless conifer. The flowers, which vary in the depth of yellow according to their age, are borne in immense sprays and remain in beauty for many weeks in summer. They are fragrant, though perhaps less strongly scented than the commoner species.

THE PINK AND YELLOW FLOWERS OF L. HECKROTTI, A FINE HYBRID OF AMERICAN ORIGIN.

L. FRAGRANTISSIMA is the winter honeysuckle *par excellence*, and is frequently confused in nurseries with L. Standishii. The former species is the more vigorous-growing bush and retains its foliage in most winters and bears rather larger and more intensely fragrant flowers. L. Standishii, on the other hand, has the advantage of flowering more abundantly, and does not seem to require such a thorough ripening of the wood to ensure a lavish crop of bloom. Both species begin to flower about Christmas in the south of England and continue until early spring. In cold districts they can be grown against a sunny wall, in which position the less vigorous L. Standishii would probably be the more successful.

L. HECKROTTI is a fine hybrid from the United States which forms a loose habited bush with pink and yellow flowers of great beauty. It apparently appreciates a very thorough ripening of its wood, and in cold, dull seasons does not do itself justice.

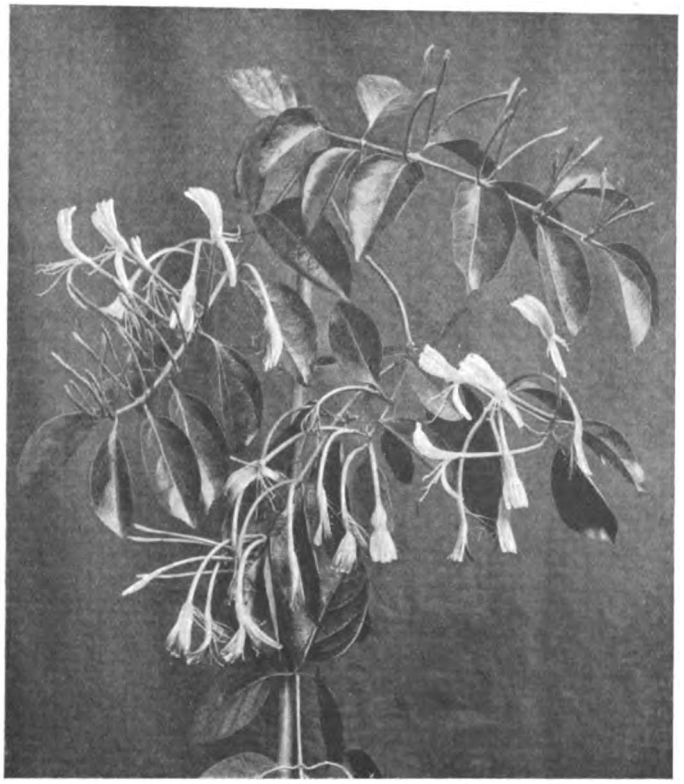
L. HENRYI is a slender, free-growing climber, introduced from China and Tibet. It is not remarkable for its flowers, which are rather small and of a curious purplish red shade; but the blackish purple berries, which are freely borne in autumn, render the plant very attractive at that season.

L. HILDEBRANDTII is certainly the noblest of all honeysuckles, but is only to be attempted outdoors in specially favoured spots in the south-west. Its large glossy evergreen leaves are very distinct, and the immense white and yellow flowers are each as much as 6ins.

Digitized by Google

in length. This grand plant likes to ramble through other plants, as it thus receives shelter from them in times of hard weather, rather than be trained out in an isolated position on a wall. Being a native of the Shan States in Upper Burma, it is not surprising that it will only grow in our warmest districts. Unfortunately, it is one of the very few honeysuckles which are difficult to root from cuttings; a very hard callus is formed which does not readily produce roots unless carefully filed.

L. ITALICA is another grand climbing species (or probably hybrid). Although known so long ago as the time of Linnæus, it is comparatively seldom seen in present-day gardens. There are several forms of it in which the amount of purple shading on the yellow flowers varies considerably. The flowers are borne in long branching panicles and are extremely showy and fragrant. It has been confused with L. etrusca, which is said to be one of its parents, L. Caprifolium being the other.



THE NOBLEST OF ALL THE HONEYSUCKLES, L. HILDEBRANDTII.

L. JAPONICA.—This is probably the most frequently planted member of the genus. It is particularly valuable for its evergreen foliage, robust climbing habit and the delicious fragrance of its flowers. In the variety HALLIANA the flowers are white, becoming yellow as they age, and the leaves are downy on each side. The variety FLEXUOSA has almost smooth leaves, and both stems and flowers are more or less purplish. There is also a golden variegated variety which is a shy bloomer and much less attractive. Owing to its powerful scent L. japonica is an excellent subject to plant outside a sitting-room window or to cover a summer-house or toolshed. Just inside the garden gate is another suitable position, where everyone who enters will be greeted by its fragrance. Once planted in good soil it requires little attention beyond an occasional thinning out of old wood and tidying up of straggling shoots. It will take care of itself on a rough bank, and layer its own stems as it rambles along.

L. MAACKII is a handsome deciduous bush honeysuckle from Manchuria, especially fine in the Chinese variety podocarpa. Like most of the shrubby species, it requires plenty of space to develop its natural habit. The bush honeysuckles are not suitable subjects for a crowded shrubbery, but are ideal for rough grassy positions.

L. NITIDA belongs to a very distinct section of the genus, sometimes even given generic rank under the name of Chamæcerasus. For neat garden hedges this is a valuable plant, as it stands cutting well. The flowers are inconspicuous and only faintly scented, so that one need have no scruples as regards clipping it in hard. Every shoot which touches the ground sends out roots, and it is a rapid grower, so that it will probably become as familiar in gardens as common privet. The fruit is a very pretty violet berry, but produced too sparsely to make the plant worth growing for the sake of berries.

L. PILEATA is another neat evergreen shrub, akin to L. nitida, but of dwarfer and more spreading habit, less adapted to hedge forming. Its violet berries are sometimes borne abundantly, and it is then a charming object; but as a rule they are scattered here and there over the plant and one has to search for each individual fruit.

L. PERICLYMENUM is our familiar native woodbine. Although so abundant in hedgerows throughout the country, it is always welcome in the garden in any of its varieties. The var. BELGICA has more purple in the flowers than in the common form, as also has var. SEROTINA (the late Dutch honeysuckle), which should be grown for the sake of its late-flowering habit. The bright red berries render the common honeysuckle very attractive until late in the autumn, and it is one of the first plants to burst into leaf in the early part of the year.

L. PYRENAICA is a beautiful pink-flowered dwarf bush honeysuckle, introduced as long ago as 1739, yet not by any means a familiar plant now.

L. TRANSLUCENS, according to the Kew Hand List, is a variety of L. quinquelocularis. It is a Himalayan bushy species whose charm lies in its white berries, which are translucent. It should be grown in a position where one can look up at the berries against the light and appreciate their beauty.

L. SEMPERVIRENS is the well known trumpet honeysuckle, one of the best of the twining species where it does well. It is a good plant for a wall or for growing on a tree in a mild district. I have seen it flourishing on an arch at a railway station in north Worcestershire. The tubular scarlet flowers lack fragrance, but are very handsome and unlike other species of the genus.

L. SYRINGANTHA, on the other hand, is a strong-growing, shrubby plant with pale lilac small flowers with a very decided fragrance. There are forms of this species in cultivation which have only faintly scented blossoms, so that it is important to select a plant raised from a really good form.

L. TRAGOPHYLLA is one of the best of the Chinese climbing honeysuckles. The scentless flowers are fully 3ins. long and are borne in large clusters at the end of the shoots. They are rich yellow in colour and very showy.

N. G. HADDEN.

THE USE OF ESPALIERS FOR GARDEN FRUIT

THE system of training fruit trees on espalier fences or to the shape known as the espalier is a very old one. Hitt, in his book "A Treatise of Fruit Trees," 1757, strongly recommended the system.

At the present time apples and pears are trained to this shape much more than any other kind of fruit though plum and cherry trees can be so shaped. It is a little surprising to us now to find Hitt recommending such fruits as mulberries, quinces and filberts for this method. Referring to mulberries, he wrote: "it produces much better fruit when planted in espaliers than from tall standards." The surprise is not the production of finer fruit, which is generally expected from a trained tree, but as one is accustomed to seeing mulberries only as fine old standard specimens, the idea of espaliers had not occurred, to me at any rate.

There are several reasons to advance in favour of the espalier tree, especially for small and medium size gardens, and there is no objection to it in the largest garden.

Where the fruit is to be grown in the kitchen garden, as it generally is, except in large establishments where a separate fruit garden is often provided, the espalier fence can be strongly recommended. It occupies very little space, and the shade

Digitized by Google

it casts is not detrimental in any noticeable degree to other crops, especially as it is almost invariably used to border the central walk although occasionally set back to act as a background to a flower border. When used in the latter way flowers should not be allowed near enough to shade the trees or to prevent the necessary attention being given to them.

If properly attended to from the start, espalier-trained trees will carry a lot of fruit of fine size and quality—this being largely due to each branch getting a full share of sun, light and air—and the fruit is seldom damaged by winds. The trees are also easily attended to. An espalier fence when the trees are in bloom or fruit is exceedingly attractive. On occasions it makes a useful and profitable dividing screen between the ornamental grounds and kitchen garden crops.

Espalier trees may be supported in various ways. Occasionally, for a few years after planting, a similar but extended form of nursery training is practised by means of upright stakes, to which are fastened smaller stakes or bamboo canes for the branches. This is not to be recommended, as it is not easy to train the trees properly, and the posts, possessing little durability have to be renewed, and in doing so the roots are likely to get damaged.

Where possible a fence should be erected in the first place. Strong supports are required at each end for straining the wires to; these posts can be of iron or wood. If the latter, oak is best. Posts 7ft. or 8 ft. long for a four-tier or five-tier fence, respectively, should be chosen. Two feet of this should be dressed with a preservative for letting into the ground. A useful size would be 5in. by 2½in. for a five-tier, but less strong would do for the lower fence. Smaller section intermediary posts could be used, or, if desired, flat iron posts with anchor feet such as are used for iron fencing would be quite suitable. If the posts are to be entirely of iron, the end ones should be of strong angle iron with anchor feet and stays to bear the strain of tightening the wires. The bottom wire should be set 18ins. from the ground level and the others at 1ft. apart, though 9ins. would be sufficient for plums and cherries.

The main point about the successful culture of espalier trees is the training and pruning. Unless this is skilfully attended to from the maiden tree upwards, the result is likely to be disappointing. It is, unfortunately, a fact that the latter is often the case. The sight is all too frequent of masses of strong shoots springing from the topmost layers, and with each annual pruning the trouble is accentuated. Having formed the tree, a perfect balance between root, branch and fruit-buds must be aimed at. To obtain this the flow of sap must be equalised in all parts of the tree, and this is largely done by pruning: summer, winter and root pruning each playing a part. When making the tree, of whatever kind of fruit, vigorous lower branches should be aimed at.

Trees with five tiers fully formed can sometimes be purchased from nurserymen who specialise in fruit trees, but the average sale tree is one with two or three pairs of branches. Since it takes a year to form each pair after the "maiden" stage, or about three and a half years from budding, to make a tree with two pairs of branches, the size naturally governs the price.

The training of plum and cherry trees into espaliers is slightly different from that of the apple and pear, inasmuch as it is advisable to allow each branch to take an upward course for a few inches before gradually bending it into its horizontal position.

The espalier-trained tree is also suitable for walls, and one frequently finds a fine old pear tree occupying the end of a house.

When planting, the distance between the trees must be partly governed by the length of space to be eventually filled; for instance, strong-growing varieties of apples and pears may be planted at 18ft. apart, but if the length to be covered is only 30ft. or even 24ft., this would take two trees of more moderate growth. In this connection the question of stock on which the tree is worked should be considered. It is possible, in the case of apples and pears, to buy trees worked on stocks the root systems of which influence the growth in varying degrees. In the case of plums, there is not the same choice, but possibly trees budded on the St. Julien stock would be best for espaliers. ARTHUR J. COBB.

APPLES AND PEARS FOR THE SMALL GARDEN

THE claims upon the limited space in the small garden are many, yet there are few gardens so cramped that space enough cannot be found to grow a judicious selection of suitably trained apple and pear trees.

With the important interests of neighbouring flower-beds, vegetable rows and the like to consider, the cumbersome and shade-giving standard trees of rambling root-run are out of the question, and for his choice the prospective planter should turn to the compact bush or pyramid trees or trim-growing espaliers and cordons.

Combining ease of management with economy of space, these handy-sized trees commence to bear at an early age, are distinctly prolific and produce fruit of excellent quality. The trained espaliers and cordons are especially well adapted for planting where space is restricted, for they take up very little room indeed and, planted against the house side, the garden wall or fence, or trained along the pathsides and borders, they will in no way interfere with crops in adjoining beds. Also, well trained trees are extremely decorative and in the utility garden might well displace the unproductive creepers and ramblers on wall or fence of almost any aspect.

The choosing of varieties to plant is a most important item. There are many points to weigh carefully, for many varieties of high culinary or dessert value are quite unsuitable for growing as dwarf trees in the small garden. Those rampant growers of untidy habit, along with those of doubtful quality and the notoriously shy croppers, should be passed over in favour of neat-growing and sure-cropping varieties of first-rate quality.

The varieties, with their season, mentioned in the following short lists will, if well cared for, conform to these requirements and provide a succession of fine fruit over a long period. That the lists might be considerably added to goes without saying, and no doubt many folk will find their "favourite" missing. However, those listed represent a select few of the several excellent varieties available. All are of sterling quality and have proved admirable for growing in the small garden.

APPLES.

For Dessert.

St. Everard, September; James Grieve, September–October; Egremont Russet, November: Cox's Orange Pippin, November–December; Christmas Pearmain, December–January; Laxton's Superb, December–March.

For Culinary Use.

Lord Grosvenor, July–August; Rev. W. Wilks, September–October; Lane's Prince Albert, November–March; Edward VII, January–April.

PEARS.

For Dessert.

Doyenne d'Eté, July; Laxton's Superb, August; Souvenir de Congrès, September; Louise Bonne of Jersey, October; Durondeau, October–November; Beurré Superfin, October–November; Conference, November; Beurré Six, December.

For Stewing.

Bellissime d'Hiver, until March; Catillac, December–April.

Generally, pears are not nearly so accommodating as apples, and unless it is known they thrive in the locality, they should be planted rather sparingly. In bleak gardens they should be grown as espaliers or cordons against a sunny wall or fence, or in a sheltered spot in the open garden where they do best as pyramid trees.

The planter should note that most varieties of these fruits are unable to set good crops, no matter how freely the trees blossom, unless their flowers are pollinated with pollen from *another* variety of apple or pear, as the case may be. For this reason it is bad policy to plant a solitary tree or several trees of one variety alone in the garden. Two or three varieties should be planted

Digitized by Google

so that flowering times overlap and cross-pollination and good fruit setting are assured.

These small garden trees should be obtained on dwarfing root-stocks, which will check exuberant growth, simplify the pruning operations and encourage early cropping. The cordon apple trees will be best on the markedly dwarfing Jaune de Metz Paradise and the espalier and small bush trees on the Doucin Paradise; or, if the garden soil is poor, on the more vigorous English Broadleaf Paradise. The pear trees should be on the Angers quince stock.

The spacing of the trees at planting time has a decided bearing upon their ultimate success or failure. With no room to spare there is often a tendency to huddle the trees together, which is a grave mistake. Seldom, if ever, should bush or pyramid trees be set less than 10ft. apart each way, each espalier should be allowed some 12ft. or more of wall space and the cordons from 2ft. to 5ft., according to the number of branches. Neither must fruit trees be planted too close to a privet hedge or to big forest trees, otherwise the competition for sunlight and root-run will be decidedly one-sided.

No elaborate preparation for planting is necessary when the garden soil has been well cultivated for several years, and beyond a deep digging in autumn, little further attention will be necessary in most cases. A moderate dressing of farmyard manure may be applied if the soil is light and "hungry," this being dug in some time before planting. Waterlogged ground must, of course, be drained and any shortage of lime made good without delay.

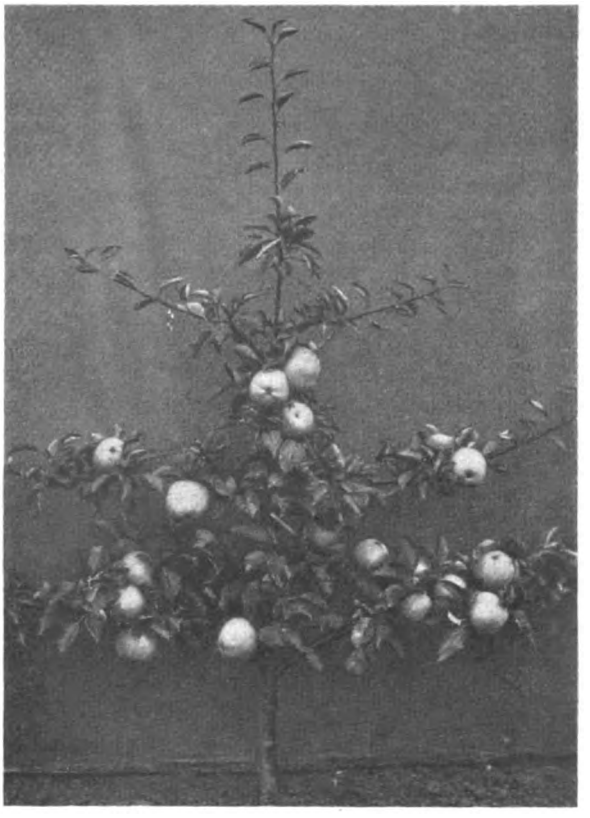
At planting time the important points to observe are: (1) To dig out the hole wide enough to take the outspread roots without cramping; (2) to avoid planting too deeply, the right depth being gauged by the old soil mark on the stem, which is the depth to set the tree now, or by the union of stock and scion, which should be just below the surface when planting is finished; and (3) to plant *firmly*. Manure ought to be kept away from the roots at planting time, but a "poultice" of rotted dung may be laid on the soil round the tree in early spring.

Unless their early shaping and training will be in skilled hands, it is not wise to purchase "maiden" or one year old trees for planting. Shapeliness and good form in after years will depend upon the quality of the knifework in the first few years, and it is better that this should be left to the experienced nursery hand.

When three or four years old the framework of branches will be well and truly laid, and at this age the bush, pyramid and espalier trees are best for planting in the garden. So simple is the training of single cordon trees, however, that these may be planted at two years old.

The pruning of the trees in after years is work of the highest importance, the aim being to regulate the shape and form of the tree, to restrict young growths so that short fruiting spurs are made along the branches and stems, and to remove dead and unhealthy wood. Both summer and winter pruning should be practised *every* year.

In late July each year the young side shoots on the apple and pear trees should be pinched back to four or five leaves from their base, but the leaders must on no account be shortened at this season.



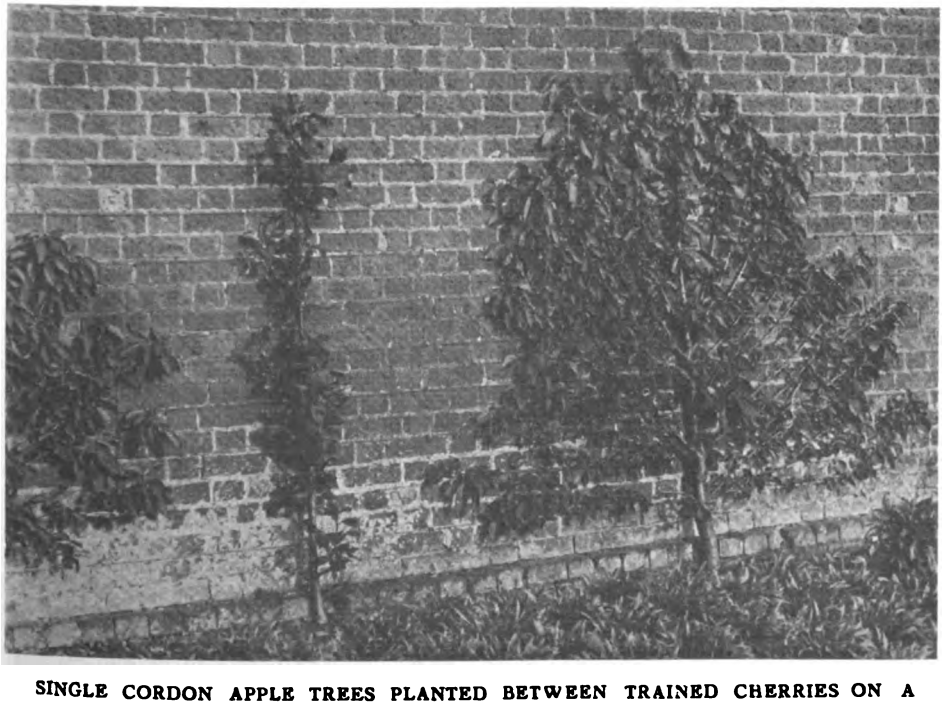
A WELL-TRAINED YOUNG ESPALIER APPLE TREE.

The winter pruning, best done after leaf-fall, is briefly as follows: With cordon and espalier trees of both apple and pear the plan is to cut back the young side shoots—shortened to four leaves or so in summer—to two basal buds. The leading or extension shoot of the cordon and the leader of each espalier branch should be shortened but slightly.

The branches in the bush apple tree should be kept evenly spaced round the top of the short main stem and the centre kept open and free from crossing growths. Side shoots should be cut back to two or three bottom buds, with the exception of those weakly growths that were not long enough to summer prune and are now no more than 5ins. long, which may be left untouched. The leading shoot of each branch should be shortened by about one-third, or by as much as half if growth is weakly.

The pyramid pear tree has no open centre, of course, there being a main central stem from which the tiers of side branches arise. The young side shoots from these should all be cut back to within two buds of their base and the leading shoot of each branch shortened by about one-third. As the trees age care should be taken to thin the crowded spurs and to shorten those becoming long and much branched. A dressing of basic slag at the rate of 4 oz. to 6 oz. to the square yard, applied in the autumn at intervals of a couple of years or so, will prove a decided help to cropping trees, while an occasional application of sulphate of potash in the month of February at the rate of 2 oz. to 3 oz. to the square yard may also be advisable.

ALAN A. RAWES.



SINGLE CORDON APPLE TREES PLANTED BETWEEN TRAINED CHERRIES ON A WALL. NO WALL SPACE SHOULD BE WASTED IN A SMALL GARDEN.

NOTES OF THE WEEK

BOX EDGING IN SMALL GARDENS.

THIS is the season of the year when many hardy shrubs change hands, among them being the box. Usually, I think, this is planted because it makes a neat edging, and, comparatively, is of slow growth, necessitating little after attention. For this reason one notices its introduction into small and moderate-sized gardens, where room is limited. It gives a finished surround to a bed, and, in certain districts, where flagged paths are favoured, it is becoming popular on either side of the walk. Large consignments arrive in this country during November and December from Holland, and these include specimen box, standards and otherwise, as well as plants suitable for edging. Skirting a garden path, box gives to a place a formal, old-fashioned appearance, which to-day at any rate is increasingly popular, and for a year or two all goes well. Once it becomes established, however, and its roots spread, trouble begins with other occupants. One has evidence of this in borders where hardy plants are located, and in beds of roses, where the unfortunate choice of a surround has been that of box. Surely if strangulation of rose trees were desired, one could not fix upon anything that would do its work quicker! How anyone having a love for roses, can endanger them by planting box as an edging, or, indeed, anywhere near them, passes my comprehension. If one must have an edging, then choose the least harmful—violas, for example—that, unlike the spreading roots of box, do not suck the soil's fertility.—CLAREMONT.

RHUS COTINOIDES.

SO much is heard nowadays of the beauties of Rhus Cotinus, with its colouring qualities and its extraordinary filmy inflorescence that gains for it its name of smoke plant, that the beauties of its close relative Rhus cotinoides are hardly ever mentioned, and yet in some respects the latter is an even more desirable plant. While R. Cotinus is an inhabitant of southern Europe, R. cotinoides is a North American species and is rare in the wild state. These two species are the only members of the genus with entire leaves, and, whereas R. Cotinus is noted for its inflorescence, R. cotinoides is a sparse flowerer and is also dioecious.

Rhus cotinoides was discovered in 1819 by Nuttall in the south-eastern United States, but was not introduced into this country until 1882, a long lapse of time between discovery and introduction for such an important plant. It is much more arborescent in its habit than its cousin, and herein lies one of its advantages, for R. Cotinus, in a locality to its liking, is inclined to grow out of hand and to become a great mass without much individuality of outline. Oddly enough, R. cotinoides is not mentioned by Professor Sargent in his Manual of Trees of North America among the sumachs which may take an arborescent form; the accompanying illustration clearly shows the tree-like growth of the specimen at Kew. Its ovate leaves have a curious translucent character that catches every ray of sunshine and enriches the colour, which is near to a blood-orange. It will grow in any soil, but probably the poorer the quality the more it will colour. Like many trees and shrubs with a large pith, it is difficult to strike from cuttings, but it is possible, if small cuttings are taken on the young side. This valuable shrub is now obtainable in the trade.—E. C.

ONE OF THE FINEST AUTUMN COLOURERS, RHUS COTINOIDES.

VIRGINIAN STOCKS IN THE ROCK GARDEN.

THAT old-fashioned annual the Virginian stock (Malcomia maritima) is one of the hardiest plants of the garden. For very early blooming it is a good plan to sow in the autumn a little seed here and there in the more sunny parts of the rock garden. Seed sown in the fall results in compact masses of plants which are crowded with bloom. These are always superior to those which come up from seed sown in the spring-time. The Virginian stock thrives best in a light soil and, if this is quite shallow, so much the greater is the chance of quick results. If the winter is fairly mild, the little plants start blossoming in February and will liven up the rock garden in a most pleasing manner. Packets of mixed seeds from reliable firms yield a fine range of attractive colours which will surprise those who have hardly thought the Virginian stock to be worth growing. The little plant is also most useful for inserting in crevices on old walls where it will continue to resow itself for an indefinite period.—S. LEONARD BASTIN, *Bournemouth*.

COLLETIAS.

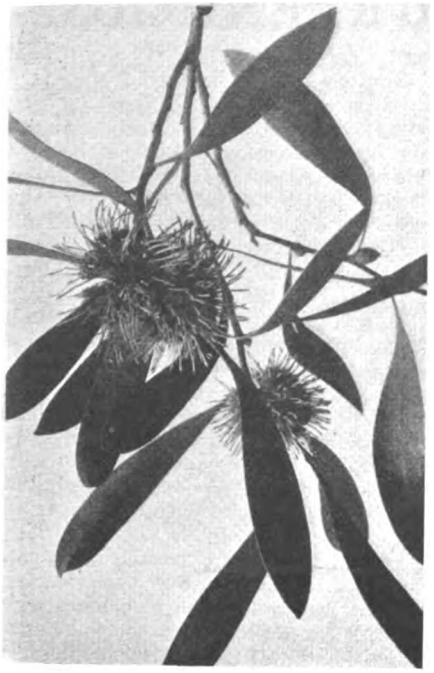
FEW more distinctive plants are to be found than the Chilian colletias. Most of the species seem to be hardy save, perhaps, in the more northerly parts of Britain. The colletias have spiny branches that are naked or, at the most, bear a few minute leaves. Perhaps the most striking is C. cruciata, the whole bush being densely covered with great curved spines placed one above the other. The plant makes a bush about 4ft. in height and it is an object of interest all the year round. Another species, C. spinosa, has an abundance of awl-shaped spines and, in the summer, is really very pretty owing to the profusion of small white flowers which it produces. Another free-flowering colletia is C. serratifolia, which, when in bloom, is a mass of silvery white blossoms. All the colletias make excellent hedges, and a barrier produced in this way is about as formidable as anything one could imagine. The colletias will grow in almost any soil, but they are much quicker in development on rather light, sandy ground. Increase is easily carried out by means of half-ripened shoots put in a close frame, preferably in the spring.—L. B.

A POPULAR EVERGREEN FLOWERING SHRUB.

WHEN, in the gardens along the shores of the Mediterranean, the autumnal rains end the prolonged summer drought and rest, and the evergreen vegetation starts with renewed activity, there is no other shrub whose flowers can rival those of Hakea laurina. They form little balls about 2½ins. across, yellow at first, but soon changing to pretty crimson, from which the pale or golden yellow long styles radiate in all directions. These flower balls are produced from the leaf axils of last year's growth on the thin, flexible and mostly drooping branches. They are a strange and fascinating sight to everybody who sees them for the first time, and as these flowers last for some time and stand shipment well, they are now grown more and more for export.

Hakea laurina or H. eucalyptoides, under which name it is generally known in gardens, is no doubt the best and showiest species introduced of this large genus. It forms a shrub 15–20ft. high, or even a small tree, with an upright and pyramidal growth, when placed isolated and left alone. Its slender virgate and pendulous branches and all the young leaves are densely covered with a fine silky felt of a metallic hue. The leaves are hard and coriaceous, oblanceolate with a blunt point and tapering towards the base, 4–6ins. long and ½–1in. wide with 3–7 parallel veins.

Unlike some of the proteaceous plants, it is not very particular as to soil. It will succeed in the stiffest and hardest limy soil, but at first it is a good plan to add some leaf-mould and sand and to keep the young plants



THE CRIMSON BALLS OF HAKEA LAURINA.

moderately moist until they are perfectly established. They will then take care of themselves and withstand the hot and dry summers, and flower abundantly every year from November to February, but especially in the autumn.

The propagation is best effected by seeds, which are produced freely, though not abundantly. The fruits are ovoid, short-beaked, wooden capsules about 1¼ins. long, with two thick valves opening when perfectly ripe and dry. They contain but two compressed seeds with very thin large black wings. These seeds should be sown in spring singly in small pots in sandy peaty soil, as the seedlings do not easily transplant. The best time for putting the young plants in their final place is the early autumn, so that the roots can get firm hold in the soil before the following summer with its dangerously long drought.

H. laurina will easily grow as a greenhouse plant and also flower, but it will never be what it is out-of-doors in southern gardens. There it is, no doubt, one of the most beautiful and popular flowering shrubs, and next to the gorgeous Dahlia imperialis, which flowers at about the same time, it is one of the glories of the sunny and mild November days on the Mediterranean.—ALWIN BERGER.

THE CLARET COLOURED MECONOPSIS NEPALENSIS.

COREOPSIS VERTICILLATA.

SOME of the coreopsis, or tickseeds, are not so hardy everywhere as one would like them to be; but one of the least grown of the genus is not only hardy, but very beautiful indeed. This is Coreopsis verticillata, the whorled tickseed, which has both attractive flowers and exceedingly pleasing whorled foliage on slender, graceful stems. It is of dwarf habit, generally from 12ins. to 15ins. or 18ins. high. I know a plant of this which has been in the same garden for between twenty and thirty years and which is as fine as ever and has only received the ordinary treatment of the border in the way of occasional lifting, manuring and replanting. It is pleasant every autumn, with its charming green leaves and its moderate sized bright yellow flowers. It will grow well in any border on ordinarily good garden soil, preferring one which is not too heavy.—S. ARNOTT.

MECONOPSIS NEPALENSIS.

THE enclosed photograph shows a meconopsis which flowered in my garden in Perthshire this summer under the name of M. nepalensis. It grows about 4½ft. high. The foliage of this species is somewhat like M. Wallichii, but the hairs on the leaves are more silvery. The flowers have four petals like M. Wallichii, but are quite a different shape and colour. In shape the flowers somewhat resemble those of M. paniculata, but are even more tubular, and quite a different shape from those of M. Wallichii, as shown by the illustration. The flowers are claret colour, being quite different in colour from any other meconopsis I know. It comes into flower in early July, and is still showing flowers at the foot of the stem at this date—the end of September. The stem leaves are much more numerous than M. Wallichii. A curious thing I notice about the petals is that they do not fall off so readily as in other species, but fade on the seed capsule, and unless picked off are apt to rot the seed capsule. The seed capsules have very dark brown hairs, quite different from those on M. paniculata, which are pale yellow.—A. HARLEY.

[*In his revision of this genus Dr. Stapf named this plant as M. Wallichii var. fusco-purpurea. In the opinion of some authorities, however, the differences between the two plants are such as to warrant the retention of the specific name of M. nepalensis.*—ED.]

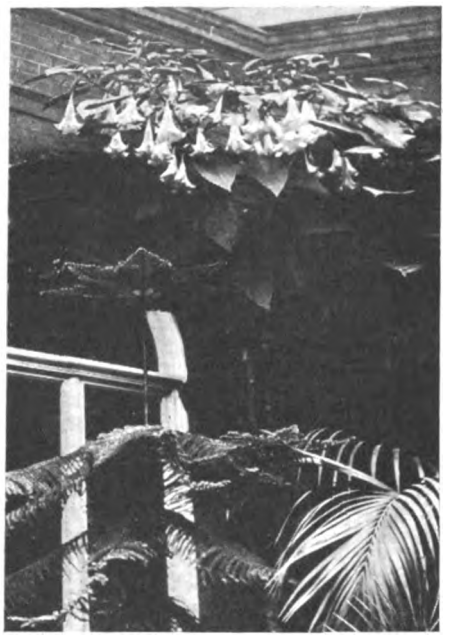
THE TRUMPET FLOWERS.

WHOEVER desires to raise his or her garden or glasshouse far above the commonplace should give consideration to the brugmansia, for while there are many imposing and gorgeous blooms to give colour and depth to our flower borders, a subject like the trumpet flower, ranking with the lily and magnolia in chaste and delicate appearance, will impart added dignity and gracefulness to the bed or border outside and the glasshouse interior, especially the conservatory or glass porch, if admitted into the general scheme of things floral.

Usually raised from cuttings, which readily strike in a moderate heat, the brugmansia progresses very well, and roots strongly, but so many fail to bring the rooted cuttings to flowering maturity. The soft-wooded stem so easily rots if given indifferent treatment, and one can even bring the plant through a whole season and then lose it by over-dampness or exposure.

If care is taken in the early stages, this will not happen. The young shrub should be grown near the glass and in a moderate temperature; in fact, it should be grown outdoors as much as possible, without in any way exposing it to very wet or cold weather, during summer and autumn, and the wood should receive as thorough a ripening outdoors as the state of the weather will permit—as late into the autumn as possible.

Culture consists first in potting in a firm soil—fibrous loam, leaf-mould, well rotted manure, coarse sand—and an occasional re-potting. When a shrub from a rooted cutting shows signs of establishment, it should be closely pruned and then re-potted as soon as the shoots begin to grow; if the stems are lightly syringed new shoots will soon appear. The pruning should always be done in the spring, before March comes to an end. Yearly treatment of this sort



A FINE SPECIMEN OF BRUGMANSIA, ADMIRABLY SITUATED.

soon brings the plant into flowering condition, and once this is attained, the brugmansia may be planted in the greenhouse or conservatory border as a permanent occupant or it may be used for summer bedding out of doors.

Properly treated, brugmansias will give two crops of flowers—one in midsummer and another in mid-autumn. Planted in the conservatory border, they will, as years go by, mount up well into the glass roof and almost hide the spot with scores of enormous white trumpets, as the accompanying illustration shows; or, kept to pots, will provide a yearly show of ornamental flowers for garden decoration. A pot containing one of these beautiful shrubs forms a most artistic and handsome object standing on steps leading to the house door, or upon a verandah or terrace. Even its large, light green leaves, without the flowers, are not to be despised as a decorative item, rivalling many an evergreen shrub that is used for this purpose. Once the plant is well established it will withstand even neglect and rough treatment, and will flourish during a spell of indifferent weather, although its blossoms suffer sadly; on this account it is best treated as a pot plant, and therefore movable, when wanted for outdoor use.—H. A. DAY.

NEGLECTED PLANTS FOR THE GREENHOUSE

IXIAS, of which there are so many beautiful varieties, are deserving of more general cultivation. They were at one time commonly grown in gardens, but at the present day I have met many young gardeners who have never seen an ixia. Their neglect is rather suprising, considering their cheapness, ease of cultivation and their usefulness for general decorative purposes. With their light graceful sprays they are ideal for table decoration. Their colours range from white through varying shades of pink, rose, red and yellow, and the beautiful green-flowered species I. viridiflora always attract attention.

Most of the ixias in cultivation at the present day are garden forms, which are sold under varietal names. Ixias for pot culture should be potted up during autumn. Six or eight corms should be placed in a 5in. pot, using a fairly light loam with the addition of some well decayed leaf-soil and clean coarse sand. The compost should be made moderately firm and the corms covered with about 1in. of soil. The pots should be stood in a cold frame, but it is better not to cover them with ashes, as some writers advise. They may remain in the cold frames until spring, when they require more head room, and should then be placed in a cool, airy greenhouse. They require cool greenhouse treatment during all stages of their cultivation, with ample ventilation on all favourable occasions, taking care, of course, to avoid draughts. After flowering, they should be gradually dried off; in fact, treated in the same way as freesias. They are propagated by means of offsets and also by seed. The seedlings take about three years to attain flowering size. The plants are so cheap, however, that most cultivators, unless they wish to make a hobby of them, will find it best to purchase fresh stock each year.

In the south and west ixias are quite hardy outdoors when planted in warm, dry and sunny borders in front of plant houses and in such-like situations. Indeed, in many places where the soil is light and warm they do well in beds in the open provided the situation is sheltered. When grown outdoors they are best planted during November. They should be planted about 6ins. deep. As a rule no protection is necessary, although it is an advantage if a thin sprinkling of straw is laid on the border, as it keeps the surface from becoming hard and caked from winter rains.

Ixias are native of South Africa, as also are the babianas, which, in common with many more beautiful South African plants, were at one time so popular in gardens, but at the present day are, for some unaccountable reason, so much neglected. This is surprising when one considers how simple their requirements are. Like ixias, they are best potted up during October, and they thrive under exactly the same conditions. They can also be grown outdoors in warm sunny borders at the foot of greenhouse walls. They are the better for a protective covering of straw, or of fibre. If so desired, planting may be deferred until February or March. There are a number of species, but very few are in cultivation at present. Some of them, like B. disticha, B. plicata and B. sambucina, are beautifully scented. Mixed varieties are still offered for sale, also the beautiful B. rubro-cyanea. This is generally regarded as being a variety of stricta. B. rubro-cyanea is indeed very beautiful, the upper part of the perianth segments being brilliant blue and the lower half a rich crimson, forming a central zone which is a wonderful contrast to the blue portion.

Tritonias, another genus of South African bulbous plants, includes some beautiful species which I am afraid are not represented in our gardens at present, but T. crocata, of which there are some fine varieties, can fortunately be obtained from dealers in choice bulbous plants. They should be given exactly the same treatment as ixias, and are best grown in 48-sized pots, placing six or eight corms in a pot. They last in flower for a long time, and also last well when cut, being very beautiful for table decoration. Alberta, Orange King and Salmon King are some of the best varieties.

Sparaxis tricolor, of which there are a number of beautiful varieties, especially the brilliant Fire King, thrive under exactly the same conditions as ixias and tritonias, and are worthy of much more general cultivation, and it is rather surprising that amateur gardeners who grow freesias, nerines and lachenalias seem to neglect the plants mentioned, for their cultural requirements are much the same, and they all do well in cold frames or cool greenhouses and thus cost little or nothing in the way of fuel. J. COUTTS.

CORRESPONDENCE

TUSSILAGO FRAGRANS.

SIR,—May I warn those of your readers who, not being acquainted with this coltsfoot, may be attracted by Mr. Bastin's description of it in his note on "Winter Flowers" (THE GARDEN, October 24th), that it is one of the most pernicious and persistent weeds that ever vexed the soul of a gardener? Some fifteen years ago I, tempted by a somewhat similar description, introduced it into my garden and I have had good reason to regret it, for it is an incorrigible encroacher; its roots will run for a great distance (hard gravel paths are no obstacles), and its huge, coarse leaves speedily overwhelm less rampant and more valuable plants. It is certainly sweet scented, but the flowers are dingy and, although it is impossible to kill the roots, the slightest touch of frost will reduce leaves and blossoms to a horrible black mass. If it must be grown, it should be planted in a sunk pot.—R. E. HEAD.

IRIS STYLOSA.

SIR,—I was interested to read in THE GARDEN for October 24th, page 601, that Iris stylosa bloomed on the 4th in a Sussex garden. I am not sure of the exact date, but about that time one of my plants had a bloom, and since then several very fine flowers have been pictured. The plants are facing south-west, against a coldhouse brick wall. There has not been any protection, ashes or anything put on their bed.—F. O. BELCHER, *Andover*.

ROSES FROM CUTTINGS.

SIR,—Your correspondent's note on the increase of roses by cuttings in the issue of THE GARDEN, October 17th, page 588, is most opportune, as this is the best season of the year to insert the cuttings. I am fully in agreement with your correspondent on the subject. At Kew we have a bed of Caroline Testout grown from cuttings taken eighteen years ago. The bushes are still full of vigour and flowering freely. In addition to the hybrid perpetuals, hybrid teas and the strong-growing teas, most of the rambling and climbing roses can be cultivated very successfully on their own roots, notably such favourites as American Pillar, Dorothy Perkins, Blush Rambler, Gloire de Dijon and William Allen Richardson. One of the great assets that roses on their own roots have is the absence of briar suckers. All the vigorous basal shoots can be retained.—A. O.

THE ZERMATT VALLEY, THE HOME OF MANY RARE ALPINES.

ERITRICHIUM NANUM.

SIR,—I have read your article on Farrers' Word Painting in the issue of October 24th with much interest. I can confirm all Farrer wrote of his day's outing in search of Eritrichium nanum, with the exception of the beauty of the flower itself, for I followed his route late in June in 1922. Our expedition was under the command of old Johan Treyer, who collects seeds for M. Correvon. After reading Farrer's description of eritrichium, I was a little disappointed when I saw it. Had I not read Farrer's

Digitized by Google

description, I should probably have said that it was the most beautiful little plant I had ever seen. But having read it, I felt that I knew the plant too well to go into ecstasies over my first view of it.

I enclose a general photograph of the neighbourhood and also one showing Eritrichium nanum, Myosotis alpestris and also M. rupicola. I have usually found the M. alpestris inhabits the zone between 3,000ft. and 5,250ft., the height lessening and the flowers growing larger and of a deeper colour as the altitude increases. From 6,000ft. to 7,200ft. the typical M. rupicola takes its place, while eritrichium is only found over 8,000ft. This is, at any rate, the case in this particular alpine area.—ASCEL OLSENS, *Kolding, Denmark.*

RUBUS ODORATUS.

SIR,—A good companion to the above which is illustrated in THE GARDEN of October 24th, is Rubus parviflorus; I prefer it to R. odoratus. It is not quite so tall, the leaves are much larger, the flower resembles a small white rose, with petals curiously crinkled. It is a strong grower, has red fruit, and is a native of North America.—R. MOORE.

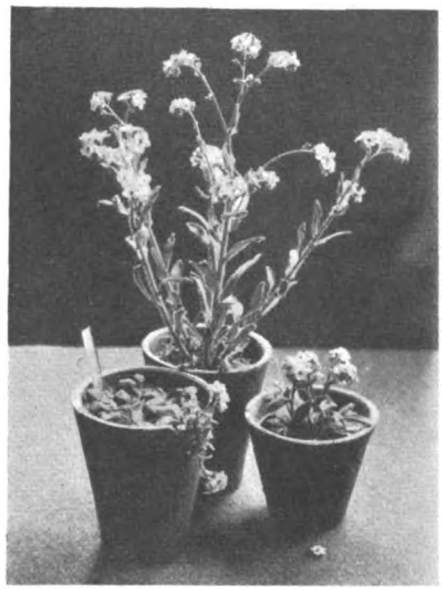
CAMPANULA CENISIA AND VIOLA CENISIA.

SIR,—In the course of correspondence with a French professor of botany I mentioned that these plants were notoriously difficult to grow in this country, and that they appeared to be definitely calcifuge. My correspondent informs me that in nature they are found in the detritus of rocks which are largely composed of calcium sulphate, from which he deduces that the plants are not really calcifuge, but merely appear to resent lime in the form of carbonate of calcium, though welcoming and apparently needing the sulphate.

If this is the case cannot some means be devised to counteract the malevolent properties of the carbonate and also furnish an explanation?—PURLEY.

COLOUR AND CATALOGUES.

SIR,—May I add a suggestion to the above subject? Would not definitions of colour terms from colour standards and nomenclatures of Ridgway give all the charts, named and numbered, that would be needed? I have seen it used by entomologists when classifying new specimens. I remember it as a book of convenient size, containing innumerable coloured plates of every conceivable shade and tint of every colour of the spectrum.—S. C. HARDING.



ERITRICHIUM NANUM IN COMPANY WITH MYOSOTIS ALPESTRIS AND M. RUPICOLA.

A FINE COLOURED CHERRY.

SIR,—I do not think I have seen any mention of the splendid autumn colouring of that beautiful tree, Prunus serrulata var. sachalinensis, sometimes called P. Sargentii. At the moment it is the loveliest bit of colour in this garden, every leaf a vivid translucent rose.—E. HUNTINGFIELD.

COLOUR NOMENCLATURE.

SIR,—Like "An Italian Reader," I, too, was greatly interested by what the Editor had to say concerning colour nomenclature. I should like, however, to reassure the writer from Italy by pointing out to him or her the following, as an example of what is beginning to be done now in English catalogues (and in a few American ones as well) from the list of Mr. Clarence Elliott of Stevenage.

"List of Plants with Blue Flowers, Alpine and Herbaceous. In this list by blue we mean blue, powder blue, sapphire blue, not violets and mauves."—(Mrs.) FRANCIS KING, *Michigan, U.S.A.*

OUR NATIONAL FLOWER.

SIR,—The Editor's note in your issue of October 17th on the rose tempts one to ask why was the rose selected for England's national flower? for within a day or two we have a bud, flower and a shattered bloom. It is true some varieties last longer than others, we also must admit that the rose is very popular, yet—

"Look to the Rose that blows about us—'Lo, Laughing,' she says, 'into the world I blow:
At once the silken Tassel of my Purse
Tear, and its treasure on the garden throw.'"

On the other hand, we have other popular old English garden flowers which last a week or two when cut; take, for instance, the border carnation. I have known blooms to last when cut as long as two weeks.—C. B. R. GARNER.

HABIT OF VIOLAS.

SIR,—Would your correspondent "H. C." who wrote a letter in THE GARDEN of July 11th on "Habit of Violas" kindly give the names with their colours, of a few violas of close-growing, neat habit for edging?—J. KENNEDY

BERRIED SHRUBS AT VINCENT SQUARE

FROM the display at the Royal Horticultural Society's Hall at Vincent Square on November 3rd last, it was clearly evident that the season was fast approaching its end. While a few exhibits of roses and carnations served to introduce a note of brighter colour and to relieve the darker lines of the evergreen foliage, the main feature was the magnificent display of berried shrubs so ably arranged and shown by the Hon. Vicary Gibbs (gardener, Mr. E. Beckett). It was a comprehensive selection, and the highest praise is due to Mr. Beckett and his staff for providing such an exhibit, which was both interesting and attractive, and at the same time of undoubted educational value. It served to indicate the increasing popularity of shrubs in modern gardening and of the infinite variety which is to be found within their ranks. Only by such displays can the attractiveness and charm of many of our shrubs be understood and appreciated, leading to their more extensive cultivation throughout the country. The genus berberis whose praises have been sung many times in these pages, was represented by numerous species, whose well fruited sprays attracted no little attention. For beauty of fruit they probably cannot be surpassed, although the cotoneasters, many of which were shown, run a close second. One or two of the most interesting shrubs which were exhibited were Celastrus articulatus, with its strikingly orange-red coloured fruits; Clerodendron trichotomum montanum, whose enamel blue fruits, with their surrounding bracts, are most attractive; and Hymenanthera crassifolia, with its tiny white berries hugging the stems closely and half hidden by the densely set small leaves furnishing the long, arching branches. Roses were there in variety and several well fruited specimens of Euonymus europæus whose beauty in full fruit is hard to beat. The snowberries were also represented by racemosus and occidentalis. A few shrubs in flower were also shown, serving to illustrate the wide latitude which exists in the shrub kingdom. There were the fine Viburnum fragrans and one or two of the diervillas and ceanothuses. Two notable inclusions were acanthopanax, laden with its densely packed clusters of black shining fruits, and Pyracantha Rogersiana, with its yellow berries.

Other shrub exhibits were those of Messrs. Waterer, Sons and Crisp, who staged many fine species of hollies and several interesting conifers, including many retinosporas, which are so handsome with their light, feathery, marbled foliage; and Messrs. Reuthe, whose exhibit chiefly consisted of conifers in pots.

Roses, carnations and chrysanthemums were the chief floral exhibits at the Show, and in spite of the recent heavy rains the roses were in remarkably good condition for the time of year. Messrs. Alex. Dickson and Sons staged a splendid group of roses, including some of the most effective and brilliantly coloured varieties for bedding purposes. Shot Silk, Lady Inchiquin, Betty Uprichard and Golden Emblem were the most outstanding. Mr. Pemberton exhibited roses of several types and among them were blooms of Padre, Isabel, I. Zingari, Mermaid and Cornelia. The carnation exhibits were very good, the blooms being large and of fine quality and depth of colour. Messrs. Allwood Bros., showed perpetuals, malmaisons, Allwoodii, and perpetual border carnations. Mr. C. Engelmann staged a fine exhibit of healthy and well shaped carnations. A magnificent vase of Laddie, with its attractive salmon pink blooms, was very noticeable. Orchids and carnations were well shown by Messrs. Stuart Low and Co.

Messrs. Keith Luxford staged an excellent display of early-flowering chrysanthemums, all of which were grown outside without any protection whatever. Messrs. Godfrey and Sons had some fine single chrysanthemums, and a general collection of decorative varieties came from the nursery of Mr. W. Yandell. A few dahlias were shown by Mr. Charles Turner, and violets by Mr. J. J. Kettle. Mr. John Klinkert showed his usual topiary exhibit, and plants suitable for pavements were displayed by Messrs. K. and E. Hopkins. Among the shrubs and climbers shown by Mr. L. R. Russell, several beautiful clematises were noticed, the most striking being the varieties Mrs. George Jackman,

Digitized by Google

Crimson King, and King Edward VII. Messrs. J. and A. McBean and Messrs. Sanders staged orchids, and the exhibits of paintings of gardens and flower portraits were welcomed back to the Show. A fine exhibit of fruit came from the gardens of Sir Nall Cain, Bt. It was well staged and the fruit excellent in size and colour.

A gold medal was awarded to Mrs. Godfery for a highly interesting exhibit of no fewer than 184 water-colour drawings of European orchids, both species and hybrids being well represented. They had all been prepared from living plants collected during the last seventeen years by Colonel M. J. Godfery, F.L.S., and showed exceptional accuracy in matters of botanical detail and correct coloration.

Messrs. Clarence Elliott showed a large and distinguished collection of alpines between a rugged background of conifers and a ribbon of gentianella. It was remarkable for certain old and robust specimens of rare or difficult plants: Saxifraga diapensioides, Azalea procumbens, Campanula Zoysii, C. Allionii alba and Pyrola rotundifolia. Eritrichium nanum was there, a seedling looking much happier than it usually does in this country, beside a gnarled old tree of Daphne rupestris.

NEW AND RARE PLANTS.

AWARDS OF MERIT.

ACACIA PLATYPTERA.—Attractive sprays of this species, which were exhibited, showed the almost orange yellow flowers in their pleasant globular heads, borne in tiny clusters, which hung gracefully from the flattened stems.

A. SUAVEOLENS.—Another attractive species whose chief distinction lies in the lanceolate phyllodes and the numerous racemes of light yellow flower heads. It forms a most ornamental shrub. These two species were shown by Mrs. Charles Williams, Churston, South Devon.

CHRYSANTHEMUM ONDINE.—An incurved variety, carrying huge flowers, measuring almost 6ins. across and 2ins. to 3ins. in depth. In colour the blooms are white tinged with green towards the centre. The florets are rather stiff. Shown by Messrs. Keith Luxford, Harlow.

C. Mrs. R. F. FELTON.—An exceedingly fine decorative variety, whose colour is most striking and attractive. The florets, of a fine deep shade of bronzy red, are stiff and well formed and lend to the whole bloom a fine sense of proportion and balance. The blooms are well carried on upright stems. It is a variety which should rapidly become popular. Shown by Messrs. Cragg, Harrison and Cragg, Histon.

C. MARY GODFREY.—This is an anemone-flowered variety and has, in its own way, a certain charm. The upstanding cushion, in the centre of the flower, is white in colour, while the surrounding ray florets are of a peculiar shade of pinkish mauve on a white ground. The blooms are medium in size and were borne well on stiff, upright stems. Shown by Messrs. Godfrey and Son of Exmouth.

ORCHIDS.

SOPHRO LÆLIO-CATTLEYA LUCIFER (L.-C. Majestic × S. L.-C. Anzac).—An elegant hybrid, particularly noteworthy on account of its rich coloration. The sepals and broad petals are mauve-purple tinged with red and having a pretty sheen, the roundly formed and large labellum of intense ruby-crimson, the tube portion marked with parallel whitish lines. Its uncommon colour is due to the influence of the scarlet colour of Sophronitis grandiflora, one of the component species of S. L.-C. Anzac. Award of merit. Exhibited by Messrs. J. and A. McBean, Cooksbridge, Sussex.

WINTER SPRAYING

SUCCESS in spraying is dependent upon a combination of scientific and practical knowledge, and of favourable natural conditions which demand a good deal of careful study. Casual, haphazard methods are calculated to end in fiasco, disappointment and waste of money.

With the spray fluids on the market, the workmanlike spraying machines for their application and the instructions for use supplied with every purchase, every gardener has the means placed within his reach to conquer the majority of the enemies that attack his fruits, plants and kitchen garden crops; and with these facts before us it is something of a reproach that the average British garden is still far from qualifying for a clean bill of health.

Investigation of reasons for failure is an excellent means of improving matters, and failure may for this purpose embrace partial successes which might reasonably be considered failures because they ought to have been completely successful.

We will spend no time nor space upon the supposition that failure may be due to carelessness in mixing sprays. It would be an insult to the intelligence of readers to dwell upon the simple fact that plain instructions supplied with sprays must be explicitly followed. One has no hesitation in saying that many failures are due to the fact that spraying is delayed until the enemy is too securely entrenched. In the case of winter sprays, for instance, it is quite a common custom to delay their application until February. The chances are that where winter spraying is most necessary one application is insufficient to make a clean sweep of the pests attacked, but by the time this can be discovered it is too late to spray with powerful winter washes.

The object of winter spraying is to get at pests or diseases which later on will have taken up an impregnable position either in the interior of fruits or beneath the surface of bark and foliage. Stronger chemicals are used because trees and shrubs in a dormant state can withstand them, whereas the same chemicals would injure young growth and foliage. Fruit trees and bushes, roses, and flowering trees and shrubs will very shortly be leafless. Why delay spraying? It is surely better to spray as soon as possible, and to make doubly sure of success by spraying again in January or February.

One of the main purposes of caustic soda wash is to rid the trunks and branches of trees of moss, lichen or algæ for the dual reason that they choke the respiratory organs of the bark, and provide shelter for spores of fungi and eggs of insects. The filth is an abomination, doing mischief every day; there can be no valid reason why it should be tolerated until after Christmas.

It would be a good golden rule never to be content with one application of any spray. A second dose will very often complete the task which, left half done, is not done at all.

An equally prevalent cause of failure is that while the principal objects of care are thoroughly well sprayed other trees about the garden, perhaps of small importance in themselves, are left unsprayed. Pests of cultivated fruits will frequently swarm upon thorns, sloes, crabs and many decrepit old trees in hedges or shrubberies, and the diseases of roses will attack hedge plants of the wild Rosa canina as well as Mme. Edouard Herriot or Lady Hillingdon in the rose beds.

If the trunks and branches of a Cox's Orange Pippin are cleaned of lichen and algæ and some old trees or shrubs close by remain smothered, it will not be long before the feet of birds, beetles, etc., carry the beginnings of a new crop of the old trouble on to the tree; and if among the slime and moss there are spores of a fungus or the minute eggs of aphides or some other insect, they too will probably be carried on to the clean tree, and the work that was so far well done will be undone because it was restricted within too narrow limits. One may justifiably point out that even a laurel, a laburnum, a double May or a quickthorn hedge is a much more pleasing possession when it is clean and healthy than when it is filthy and sickly, and, even apart from the risk of contamination of fruit trees, it is desirable while the spraying machine is in use to spray everything that needs it. The gardener who sprays has a real grievance against negligent neighbours who will not spray. Because a garden owner is too careless to trouble about keeping his trees and plants free from pests and diseases his more enthusiastic and energetic neighbour may be defeated in his efforts to keep his fruits and flowers in a clean and healthy state; and the good work of one who perseveres in waging war upon garden foes is undone by a neighbour who allows his garden to be a sanctuary and breeding ground of all manner of pestilence. That point of view has not been sufficiently stressed or we should surely find less cause for complaint. It is an undoubted fact, however, that the pace of progress is severely hampered because spraying is not conscientiously practised from a sense of public duty as well as for personal benefit.

Spraying should not be deemed to concern the cultivator of orchard fruits alone; everyone who has a gooseberry bush or currant should be interested in keeping it clean. Rosarians should spray in winter as well as summer—for black spot, mildew, rust and aphis will succumb to winter sprays more surely than to the softer sprays that can be used in summer. A. J. MACSELF.

THE NATIONAL CHRYSANTHEMUM SHOW

As the chairman of the Committee suggested at the Annual Show of the National Chrysanthemum Society on November 5th last, the greatest thing our raisers have done for the flower is to extend its season from a brief four weeks in autumn to one lasting from July to March. And, while the dates given are perhaps the extreme limits of flowering, they are approximately correct.

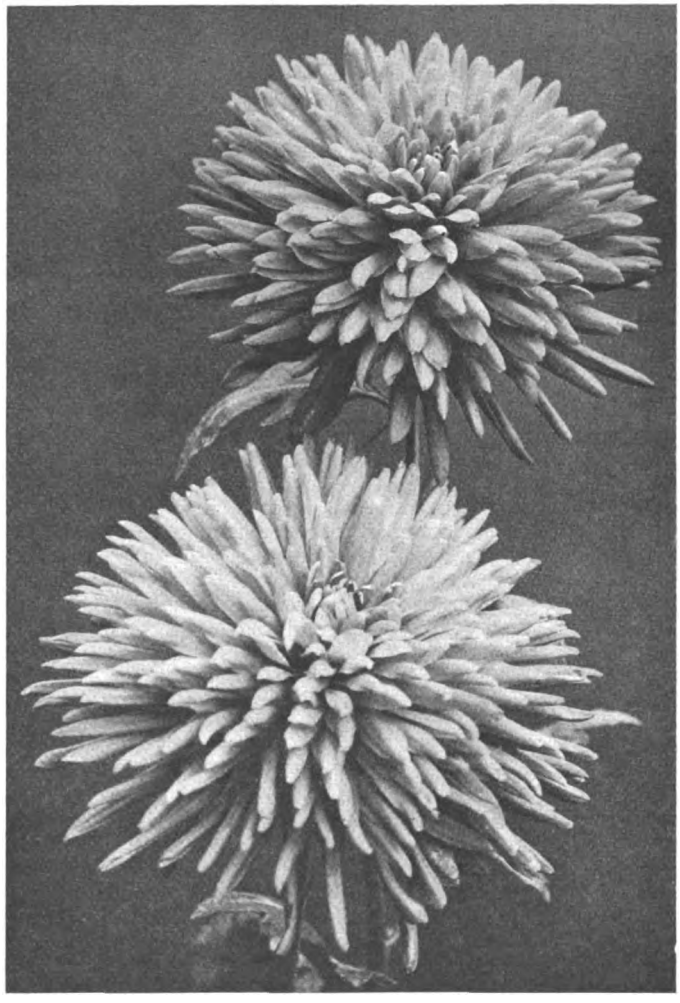
There are those among us whose floral fancies lie in the hardy flower border, who would wish the Society would turn its attention towards the early-flowering varieties and encourage the raising of dwarf varieties which one could plant and feel reasonably confident that, as with the average border perennials, they would continue for four or five years. But, unfortunately, the present-day border chrysanthemum is a tender plant.

But our present concern is rather with the greenhouse varieties which are in flower at the height of the chrysanthemum season, and particularly with those seen at the Show. That the popularity of the Queen of Autumn Flowers, which title its devotees claim for it, continues unabated is evident from the enormous attendance. During most of the afternoon of the first day of the Show it was a difficult matter to make any but the very slowest progress in the hall and was well nigh impossible to make any real inspection of the magnificent trade groups.

As with all flower shows, it was the trade specialist who provided the most spectacular exhibits. Mr. H. J. Jones has set up many collections of chrysanthemums during his long career, but we doubt if ever before he has equalled that of the present occasion. He occupied the whole of the end of the hall, and there he set up a most magnificent display. Along the back he had huge stands of the best exhibition Japanese varieties. There were the rich yellow Mrs. R. C. Pulling, the white Queen Mary, Nan Luxford of soft pink shading, Mrs. C. Swaisland of enormous size and lilac-pink colour, Red Majestic (a brighter counterpart of the popular exhibition variety), Chastity of the purest whiteness, Sulphur Queen and many other sorts. Each of the numerous blooms was perfect of its variety and equal in quality to the finest in the competitive classes.

But Mr. Jones does not confine his attention and energies to those monsters of the chrysanthemum world. He has a warm corner in his heart for the formal incurved type and rightly insists that these favourites of bygone days will "come again" when their great decorative value will be fully appreciated. The truth of this was well evidenced in the stands of Golden Thorpe, which contained two dozen or so perfect blooms of rich golden yellow, and in another of the white A. W. Thorpe. Other good varieties of this type are Captain Kettle, crimson with golden buff reverse; J. W. Streater, delicate creamy primrose; Romance, rich yellow; and Mahogany, of reddish mahogany colour. Among the single-flowered varieties in this group we especially noted Pink Beauty, Mrs. Palmer, white; Mrs. F. Brill, pink with white zone; and the rich yellow Phyllis Cooper. The other types—the market varieties, the anemone-flowered, the spray-flowered and the spidery petalled—were also well represented in this unique collection, which was given the large gold medal.

Also of great interest and value was the large group of Messrs. W. Wells and Co., which occupied a large space just inside the hall. Their medium-sized Japanese varieties, most of which produce half a dozen or more flowers of great value for house decoration, made a splendid show. The very best of the many sorts were Gloriosa, bright golden bronze; Liberty, crushed strawberry; Phoebe, silvery pink; Market Red, velvety blooms; Ethel Thorpe, bright mauve; Harmony, bright reddish orange; Huntsman, rich crimson; In Memoriam, velvety crimson; Ivy Gay, mauve; J. W. Streater, golden yellow; and Mme. H. Foreau, purple. Besides their great value as cut flowers, the above are of dwarf habit and make splendid plants for large vases. Captain Kettle, a crimson and gold incurved variety, and R. Hooper Pearson, richest yellow, were also most attractive. Although these sorts were very prominent, the large exhibition varieties also filled many vases, and they included Mrs. B. Carpenter, Majestic, Mrs. Algernon Davis, Mrs. Harold Wells, Mr. George Munro and Queen Mary.



THE HANDSOME CRIMSON BLOSSOMS OF MRS. R. F. FELTON.
Shown by Messrs. Cragg, Harrison and Cragg.

Many excellent single-flowered varieties were staged by Messrs. Keith Luxford and Co. The very best were Nona, pure white; Oriole, yellow; Everlasting, a flower of great substance and rich crimson colour with a narrow pale yellow zone; Phyllis Cooper, rich yellow; and Ethne, pale bronze stippled over golden yellow. Very many exhibition Japanese varieties were included in this interesting collection, and the chief were Julian, rosy buff; Mr. T. Slack, pale crimson, almost scarlet; Nan Luxford, silvery pink; Thomas W. Pockett, rich pink with silvery reverse; Majestic, golden amber; and Mrs. George Monro, velvety crimson.

The graceful spray-flowered chrysanthemums were seen to much advantage in the exhibit of Mr. William Yandell, where we were reminded that the old variety Source d'Or is still of great value. Market Red, Scarlet Sunshine, Rosalind, reddish terra-cotta; Miss A. Brooker, crimson chestnut; and Stanton are the names of only a few of his good sorts. Queen of the Pinks, of uncommon and fascinating form, was largely shown by Messrs. W. Godfrey and Son, who also had their new pale yellow single called Devonshire Cream, with Dignity, November Glow, Gorgeous, Ruby and others of this useful type; while Mr. A. G. Vinten set up good vases of Shirley Scarlet, Exmouth Pink Miranda (glowing scarlet), Raleigh (deep crimson) and Phyllis Cooper.

No doubt owing to the high cost of transport, plants are not shown so much as formerly, but Mrs. McDowell Nathan sent from her gardens at Little Heath Wood, Potters Bar, a group of particularly well grown plants and was awarded a gold medal. Mrs. Nathan was also very successful in the competitive classes, especially with the large Japanese blooms shown in vases.

A specimen plant of Mrs. K. Luxford bearing over sixty more than medium-sized, brightly coloured blooms excited a deal of admiration. This perfect example of the specimen plant was sent by Mrs. Fox of Melmouth Lodge, Cookham. The Swanley Horticultural College had a graceful group of pot chrysanthemums near the annexe.

The competitive exhibits again reached a high standard of excellence, and most of the many classes were well filled. We were glad to find that the principal classes for the large exhibition blooms shown in vases were more popular with the visitors than the arrays of specimen blooms set out in congested rows on show boards, though we realise that quite a number of growers still adhere to the formal method, of which there were six exponents of thirty-six distinct varieties, and Mr. E. Mocatta of Woburn Place, Addlestone, again won the first prize and that for twenty-four varieties.

In the more interesting classes for similar magnificent flowers in vases the principal first prizes were won by Viscount Hambledon, Greenlands, Henley-on-Thames, and the Lord Wandsworth Agricultural College. Lord Terrington, Spinfield, Marlow, was first with twelve delightful incurved varieties in large vases.

Digitized by Google

There were not so many exhibits of single chrysanthemums as usual, but Mr. F. J. Yarrow, St. John's Wood, won the George Monro Cup with twelve splendid vases of such varieties as Miss Joyce Moore, Audrey, William Smith and Crimson Velvet. Audrey was a beautiful orange yellow variety, Crimson Velvet a crimson with yellow disc, and Miss Joyce Moore, a large crimson.

NEW CHRYSANTHEMUMS.

The Floral Committee had a large number of new varieties to consider. Mary Godfrey, Mrs. R. F. Felton and Ondine, which had already received the R.H.S. award of merit, were given first-class certificates.

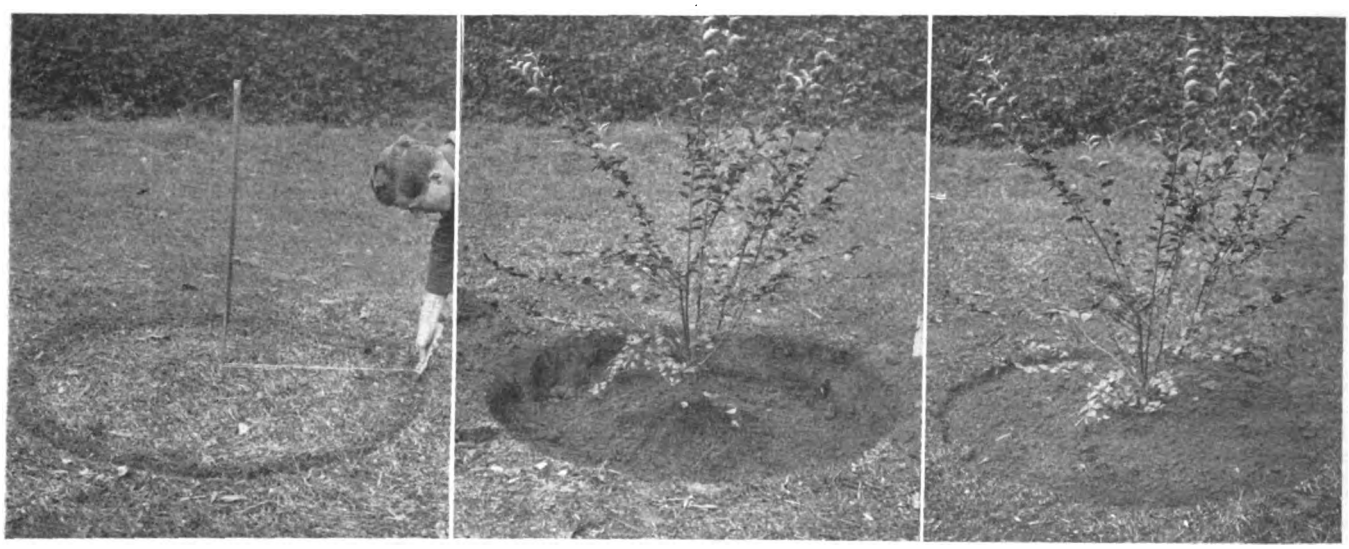
AWARDS OF MERIT.

MRS. A. HOLDEN.—A magnificent exhibition Japanese variety of rich terra-cotta colour flushed with crimson and showing an old gold reverse. Shown by Mr. G. Carpenter.

RONA.—A medium-sized single of perfect form and rich crimson amaranth colouring. Shown by Mr. H. Woolman.

No. 6.—Is the best rosy crimson sport from Bronze Molly we have seen, and it possesses considerable decorative value. Shown by Mr. A. G. Bendir.

THE PLANTING OF SHRUBS



1.—THE MAKING OF THE RING PRIOR TO DIGGING.

2.—PLANT IN POSITION WITH ROOTS CAREFULLY SPREAD OUT ON THE SOIL.

3.—PLANTING COMPLETED, NOTE THE COLLAR OF PLANT IS AT SOIL LEVEL.

ONE of the first questions to be considered in connection with planting shrubs is the best time for the work. Most deciduous shrubs can be moved successfully from the end of October until the beginning of April, when the weather is mild, and the ground in good condition for working. There are a few exceptions. Magnolias, for example, move best towards the end of April and early in May. A very good time to move M. conspicua and M. Soulangeana is after the flowers are over when new growth is beginning. With the majority of deciduous shrubs commence planting in late autumn, when the leaves turn colour, and begin to fall.

With regard to evergreens, unless they can be moved with good solid balls of soil attached to the roots, the subject is not so easy. September and October, or April and May are the best periods to plant hollies, yews, evergreen oaks, etc. The greatest enemy of newly planted evergreens is cold, drying winds. Evergreen rhododendrons are an exception. These invariably move with good large solid balls of soil holding the roots and can be safely moved from September to April in open weather.

PREPARATION OF THE SOIL.

This is an equally important subject in the cultivation of fruit, flowers, vegetables and shrubs. In some gardens, however, as far as shrubs are concerned, they receive the least attention of the four, yet the future growth of the shrub, to a considerable extent, depends on the preparation of the ground. For vegetables and herbaceous plants the soil is, or should be, frequently deeply dug, but, except for possible thinning, one expects shrubs when once planted to grow undisturbed for many years.

The best soil for the majority of shrubs, if it is possible to choose the ground, is a deep, well drained loam. For shrubs a depth of 2ft. should be cultivated by what is termed "bastard" trenching. By this method the bottom 1ft. of soil is thoroughly broken up, some manure, or decayed garden refuse mixed with it, but left at the bottom. The top 1ft. is likewise worked and kept at the top. In gardens with a poor or in some way unsuitable sub-soil, considerable work will be desirable in the preparation of beds and borders for shrubs. A proportion should be removed, how much will depend on local circumstances, and replaced with top-spit loam, decayed garden refuse, bonfire ashes, leaf-mould, old potting soil, in fact anything suitable to improve the ground.

When planting single specimen shrubs on a lawn, a hole should be prepared much larger than at present required, so that for some years after planting the roots have a good area of fine soil in which to grow. The station prepared should be at least 6ft. in diameter, and 2ft. deep, 8ft. diameter is better for large growing shrubs. If necessary a proportion of the ground can be turfed over after planting.

A CULTIVATED RING

should be kept round all specimen lawn shrubs. Experience very definitely points to the better health of shrubs when the ground is surface cultivated, than when grass is allowed to grow close up to the stems. Also mulching and feeding with manures is much easier to undertake and more satisfactory.

The question of pruning at planting time is a subject which should have attention. However carefully the work may be done, there is usually some damage and loss of roots. To balance the check caused by transplanting, some shortening of the longer shoots is desirable. The actual amount may vary according to the size of the bushes, the number of roots, and whether the move has been a good one, or the roots rather damaged in the transplanting.

Independent of the shifting, it is often convenient at planting time to thin out crowded branches, removing old or thin weakly twigs, in addition to shaping the bushes. This I can picture being done with philadelphus, diervillas and spiræas, even though the plants may be only three or four year old plants, from the nursery, or during the thinning out of a recently planted shrubbery bed or border.

With regard to evergreens, thinning and shortening of the growths is most desirable, unless they are moved with large, solid balls of earth. Transplanting must check the flow of moisture from the roots, to balance which, and reduce the amount of transpiration, the twigs and evergreen leaves in particular should be considerably reduced. I have on occasion seen a holly, which moved rather badly, saved by picking off most of the leaves.

Digitized by Google

Deep planting is the cause of many losses among trees and shrubs, more particularly in the case of plants with a clean stem near the ground level. The bark is buried perhaps only a few inches, but with some plants this is sufficient to kill the bark and underlying tissues, stopping the flow of food from the roots to the branches. Rhododendrons and lilacs in particular suffer from deep planting. The fact that a bush or tree is planted too deeply may not be apparent for some few years. It really amounts to a case of slow starvation by the gradual cutting off of the food supply, noticeable in the declining health of the plant. It is easy to plant a shrub so that it will be eventually too deep. The ground is trenched to a depth of 2ft. or more, the soil trod firm and planting done in the orthodox way. The soil, however, is not replaced so firmly as before, hence if the plant is not left rather high to allow for the sinking of the loosened soil, there is the chance of the stem being eventually buried. This is only likely to happen when single specimens are planted. In the entire trenching of beds and borders the whole of the ground naturally sinks together in time.

It is very desirable to water all newly planted shrubs of any appreciable size. This not only assists in settling the soil around the roots, but makes available an abundance of moisture for the disturbed roots. If transplanting is done early, when the soil is still warm, this materially hastens the making of new roots. In the case of evergreens watering at planting time and during dry weather, until the plants are established, is practically essential. A. O.

GARDEN TECHNIQUE

Notes on the Technical Side of the Garden and the Cultivation of Plants.

SAVOY DWARF GREEN CURLED.

TO look upon a good breadth of this winter cabbage in October or November is as much a charm and joy to the interested cultivator as is the gay display made by some choice flowering plant.

This variety of Savoy is mentioned in Nicholson's "Dictionary of Gardening," and it is still one of the foremost kinds in cultivation, and gets a good name all round. "An excellent and distinct variety," "The best for general crop," and "A good winter variety," are some of the encomiums heaped upon this variety. Like most of the brassica family the seed should be sown on a prepared seed bed in spring, and the young plants set out at 18ins. distant from each other in an open sunny position in June; then the plants get sufficient time to grow and mature before severe weather sets in.

Early in February of this year we had a section of ground—on which the old asparagus beds had been situated—thoroughly trenched and manured, the bottom soil being brought to the surface. On this ground our Dwarf Green Curled savoys have grown exceptionally well.—D. A.

THE TREATMENT OF DEFECTIVE VINE BORDERS.

REALLY well constructed vine borders, although affording the best results in every way, will not last indefinitely without some attention being paid to them. The badly constructed border is a source of trouble almost from the beginning, and renovation is a difficult matter when the roots are in it. Still, it is possible to improve such borders during the winter months, and there are many defective ones requiring urgent attention. The chief defects are bad drainage, unsuitable soil and consequent sourness of it, which has an ill effect on the roots, as the latter cannot live in such soil, much less continue to increase as normal roots should. If the grapes shank, if the leaves become sickly yellow and crack around the edges, there is not any doubt that the roots of the vine are not active, and it may be that many of them are dying. The surface soil should be carefully taken off till the roots are bared; if the latter are fibreless and the rind or bark on the largest is brown and greasy to the touch, there is sufficient evidence that the soil is in a bad condition. If the drainage is wrong, lay pipes to an outlet near by to rectify matters. When the roots are bared on the surface, carefully collect them, tie in small bundles, spray with water and wrap them in wet sacking; keep the latter moist while as much old soil as possible is being removed and new fibrous loam placed in. Firm the new loam, spread out the roots and cover them with 4ins. of loam and old mortar rubble. Only add finely ground bones, not any organic manure.—HANTS.

RE-POTTING SHOW PELARGONIUMS.

THE cuttings of these are rooted from the end of July up to a month later. In some instances the cuttings, when not too hard, form roots quickly; when hard they are a long time in making sufficient roots to warrant the cultivator in distributing them, as must be the case when potting singly takes place. Late inserted cuttings should be placed singly in small 60-sized pots, it will then be unnecessary to disturb them before the first week in February. Where a number have been inserted in larger pots and a warm greenhouse is available, the potting-off may be done now, in preference to leaving them in the cutting pots nearly all the winter. The thing that matters most after the potting is watering. The soil must never be in a sodden state nor allowed to get dust dry, though the latter condition is the safer. Fibrous loam two-thirds, leaf-soil one-third, with a sprinkling of old mortar rubble, will form a suitable compost. All that is necessary is to have clean, dry pots and crocks. The roots *a* are tender, break up the soil *b* carefully so as not to bruise them. Have sound drainage *c*, and pot moderately firmly, so that the roots *d* are not unduly pressed down and broken off. A potting stick is unnecessary.—GEO. GARNER.

THE CULTURE OF ARUM LILIES.

THE Nile lilies (Richardia africana) are easily managed plants, and can, if desired, be had in flower at Christmas. Each year about the middle of August we turn the plants out of their pots, where previous to this time they have been out of active top growth. The strongest crowns, or suckers, are then selected and five of them placed quincunx style in each 12in. pot. In the potting compost, which should be fairly rich, we intermix some well decayed farmyard manure, which the Nile lily enjoys. After potting, the plants are placed in a frame and given no water at the roots for a few days, but sprayed over and between the pots on all fine days. This, in conjunction with keeping the frame closed, provides a genial atmosphere, and the plants are then encouraged into growth. As soon as the plants have made headway, a little air is admitted to the frame on favourable occasions, but genial growing conditions are maintained. These cultural details are followed until such time as the plants are set in one of the glasshouses, when they should be staked and matting run round the stakes, as growth advances. Our plants this year are strong and healthy, and at present—the last week of October—many rolled up flower spathes are showing above the beautiful green foliage. The plants are situated in the carnation house, and are therefore not unduly hastened by artificial heat.—DAVID ARMSTRONG.

DAHLIAS FROM SEED.

I WONDER how many of your readers try raising their own plants or tubers from seed. I have had great success with them this season. I sowed seed about the middle of January in heat 55° to 60°. They germinated in ten days, and I then brought them into a cool house and potted them off into thumb pots on showing rough leaves. I next potted them on into 60-sized pots and from these into 4in., keeping them on a shelf near the glass, and gradually hardening them off till I put them out in May. I planted them 2½ft. apart, and by the end of July they had covered the whole border, where they kept a uniform height throughout the season. The first blooms were out on July 10th. They had plenty of manure and were given a mulch. The variety used was Sutton's Star. —M. MASON.

MAKING A PEACH TREE BORDER.

ALTHOUGH it may be a very easy matter in the case of the expert, it is a difficult operation for the inexperienced cultivator to carry out without some instruction. Even in the open air peach and nectarine tree borders must be carefully constructed if good crops of fruits are to be reaped. But I am referring to borders for trees grown under glass, chiefly, in this note. Presuming the natural soil to be a retentive clayey one, the efficient drainage of such should be the first consideration. The position—site—has an important bearing on this part of the work; if the ground slopes naturally in one or more directions, the border may be made so that the surface is on a level with the surrounding ground and a good layer of drainage material with a pipe outlet will ensure efficient drainage. If the site does not permit of any outlet and the soil is clayey, then it will be best to have a slightly raised border, a very good drainage layer and a few pipes laid to a deep "soak" or well just outside the house. In addition to this, some drain-pipes should be laid among the basal material and more ordinary drain-pipes fixed upright in the border at a distance of 5ft. apart. These should have wire netting on the top

Destroy them Now!

The eggs of those pests that will hatch out next Spring and spoil your fruit and rose trees, can easily be destroyed **NOW** by using the Famous

"Ferry" Brand Winter Wash

Trees cannot make healthy vigorous growths and bear abundant fruit and flower, if they are burdened with loose bark, moss and lichen, behind which pests can hide. "FERRY" BRAND WINTER WASH should be applied while the trees are dormant. All mossy growths and insect pests will be destroyed without harm to the tree.

does much of the thinking for you. There is no book so up-to-date, so easy to understand, or so reliable.

Published by
"COUNTRY LIFE" LTD.
20, Tavistock Street, Covent Garden, London, W.C.2.

to prevent soil and blocking matter entering, and be about 4ins. above the border surface. The drain-pipes, so placed, will ensure ventilation of the border and sweetness of the compost in the latter. If the natural soil is light and the site good for drainage, then ordinary rubble material in the bottom will answer without any pipes. The approximate depth should be about 2ft. of prepared compost.—G. G.

OBITUARY.

MR. JAMES WHITTON.

IT is with profound regret that we have to announce the death, on October 30th, of Mr. James Whitton, J.P., V.M.H., the late Director of Parks, Glasgow. Mr. Whitton, who was born at The Gardens, Methven Castle—where his father was head-gardener for about half a century—in 1851, served his apprenticeship at Thirlstane Castle, and remained there as journeyman until he went in the latter capacity to Glamis Castle, the seat of the Earls of Strathmore. After his promotion as foreman at Glamis, he was appointed head-gardener to Mr. Houldsworth, Coltness, Wishaw, where he remained for some years until he was offered and accepted the post of head-gardener at Glamis Castle. In 1893 he received the appointment as Superintendent of Glasgow Parks, and held this appointment, later entitled that of "Director of Parks and Curator of the Botanic Gardens," until his retirement on May 31st, 1923, when he was succeeded by Mr. Edward Matthews.

Mr. Whitton had been in failing health for some time, but it was only latterly that his illness took a serious turn and after some weeks' confinement to bed he passed away at his home, Bellahouston House, Glasgow.

His eminence as a horticulturist and arboriculturist is well known to all interested in these crafts, and it is needless to expatiate upon the ability with which he managed the huge responsibility of the directorship of the Glasgow parks, only five in number on his appointment but increased to thirty-one with many open spaces, at the date of his retirement. The Glasgow parks are recognised as models of their kind, and witness in the highest degree Mr. Whitton's zeal, energy and ability. In wider circles he was well known as an expert of the highest skill. The Royal Horticultural Society conferred upon him the coveted Victoria Medal of Horticulture, and his services as juror were highly appreciated at international and other horticultural exhibitions at home and abroad. His knowledge of and love for arboriculture also led to his holding high offices in various societies for the encouragement of forestry.

PUBLICATIONS RECEIVED.

"Insecticides, Fungicides and Weed Killers." A practical manual on the diseases of plants and their remedies, by Dr. E. Bourcart. Second English edition revised and enlarged. Published by Messrs. Scott, Greenwood and Son, 8, Broadway, Ludgate Hill, London, E.C.4; price 18s.

GARLIC—A NEGLECTED VEGETABLE

IT is a far cry from gardening to garlic, but I think I should be failing in my duty to my fellow creatures were I not to write a few kindly words on behalf of this misjudged vegetable. Lest it should be imagined that my customary lunch is a bowl of garlic and a hunk of bread, as is so popular in southern Italy and Algeria, I hasten to add that I like my garlic, as indeed most other things, in moderation; but moderation in the use of garlic is difficult to find. I had dinner at a restaurant the other night where they should have known better, and I asked to have the salad bowl rubbed around twice with garlic before the lettuce was added. The waiter either misunderstood or pretended to, and to my horror proceeded to sift chopped garlic out of a gigantic caster over my salad. That is an object lesson how *not* to use garlic.

The truth is that no English, Scotch or Irish cook knows how to use garlic—or, for that matter, sage. I have had to give up roast goose and stuffed veal because of the abominable amount of sage that is always added to the stuffing; but sage is a coarse and crude weed, not to be mentioned in the same breath as garlic. Good cooks laugh at sage and look upon it as a deodoriser. If a cook is given garlic in this country, she begins by using it as an onion and, after terrific complaints, becomes frightened of its potency and gives it up in fear and trembling. Overdone it is a curse which follows you around for days, but used in the right proportion it gives a zest to many an uninteresting dish and imparts a peculiar, indefinable, nutty flavour which nothing else gives. There is something elusive about its charm that lovers of a trace of it can never fathom.

There is only one rule that must be followed in the use of garlic; it should never be so strong that it destroys your appreciation of the next dish. It should never be used either whole or chopped up in a dish unless by an experienced cook. The method is simple; it should be rubbed round the inside of the pot or dish, and the proportions are given by less or more rubbing. The obvious use that comes to everybody's mind is in a salad. Take a clove of garlic between finger and thumb and press it firmly on the inside of the salad bowl. Run it around the inside two or three times and it will improve any salad, provided, of course, that oil and vinegar dressing is used. Here may I also add how a little chopped tarragon improves a green salad; it gives it a piquancy that is often lacking.

There are dozens of dishes which are raised above the ordinary by the faintest trace of garlic in their make up. Tripe and onions, strange though it may seem, is one that is vastly improved by a clove of garlic being rubbed on the inside of the stewpan, while a calf's kidney stewed in a little stock to which a glass of dry white wine has been added and with the bottom of the pan well rubbed with garlic is an extraordinarily good dish. The sauce is, of course, a little watery and rather a muddy colour, but appearances are deceptive. If you dislike the look of it, a little boiled rice or mashed potatoes can be added to soak up the sauce.

Now as a solace for having read so far with me in my defence of garlic, I will give you a recipe for cooking potatoes that is not common and is always a success. It has a name in French of considerable length, but I have forgotten it. Rub the bottom of an earthenware or glass fireproof dish vigorously with a clove of garlic, about six hard rubs is sufficient, then cover the bottom with a layer of slices of raw potatoes about a third of an inch thick; they can be either flat or overlapping. Sprinkle them with salt and pepper and add a lump of butter the size of a large walnut. Then pour in milk until the potatoes are just covered and put the dish in a moderate oven for half an hour or so. When the milk is completely soaked up the dish is ready. Serve very hot. It is so good that it is a meal by itself, but here again is a case where the dish is made by the trace of garlic. Without it, it would be a vegetable; with it, it is a dream.

Garlic has been grown in the British Isles for centuries, and at one time was used extensively in the pharmacopœia. It is not often seen in gardens nowadays, and perhaps it is hardly worth growing, for a little goes such a long way. Still, whether it is grown or not, it could certainly be used a little more in our cooking.

E. H. M. C.

THE MOCK ORANGES

NO SHRUBBERY BORDER IS COMPLETE WITHOUT THEM. THEY CAN BE PLANTED DURING THIS MONTH IN FINE OPEN WEATHER.

THE philadelphuses form one of five large genera of hardy shrubs belonging to the saxifragaceæ and are closely allied to the deutzias. Cultivators handling large numbers of hardy shrubs can usually separate most of them at a glance by their appearance in growth. The important botanical distinctions are that the single-flowered philadelphus has usually four petals, four calyx lobes, a large number of stamens and simple hairs; while the deutzias have five petals, five calyx lobes, ten stamens and stellate hairs.

CULTIVATION.

Few families of hardy shrubs are more easily propagated by cuttings. Soft shoots root freely under glass during July and August—the earlier date is preferable, together with a gentle bottom heat; during August insert in a cold frame or under a cloche. Cuttings made of ripened wood will root on a border outside if inserted during October and November. Suckers, or offsets, and layering also provide ready means of increase. The mock oranges are also easy to raise from seed, from which, however, they may not come true.

From the way the common mock orange grows and flowers every year in small gardens and shrubbery borders, with comparatively little, if any, attention, it is obvious they will grow satisfactorily in most soils. Few hardy flowering shrubs, however, give a better return for attention in the liberal preparation of the ground. A rich loamy soil is the best, but ordinary garden ground trenched 2ft. deep can be made very suitable for philadelphus by adding humus from the garden refuse heap, bonfire ashes, leafmould and decayed manure. If the soil is very poor a good dressing of fibrous loam is worth while.

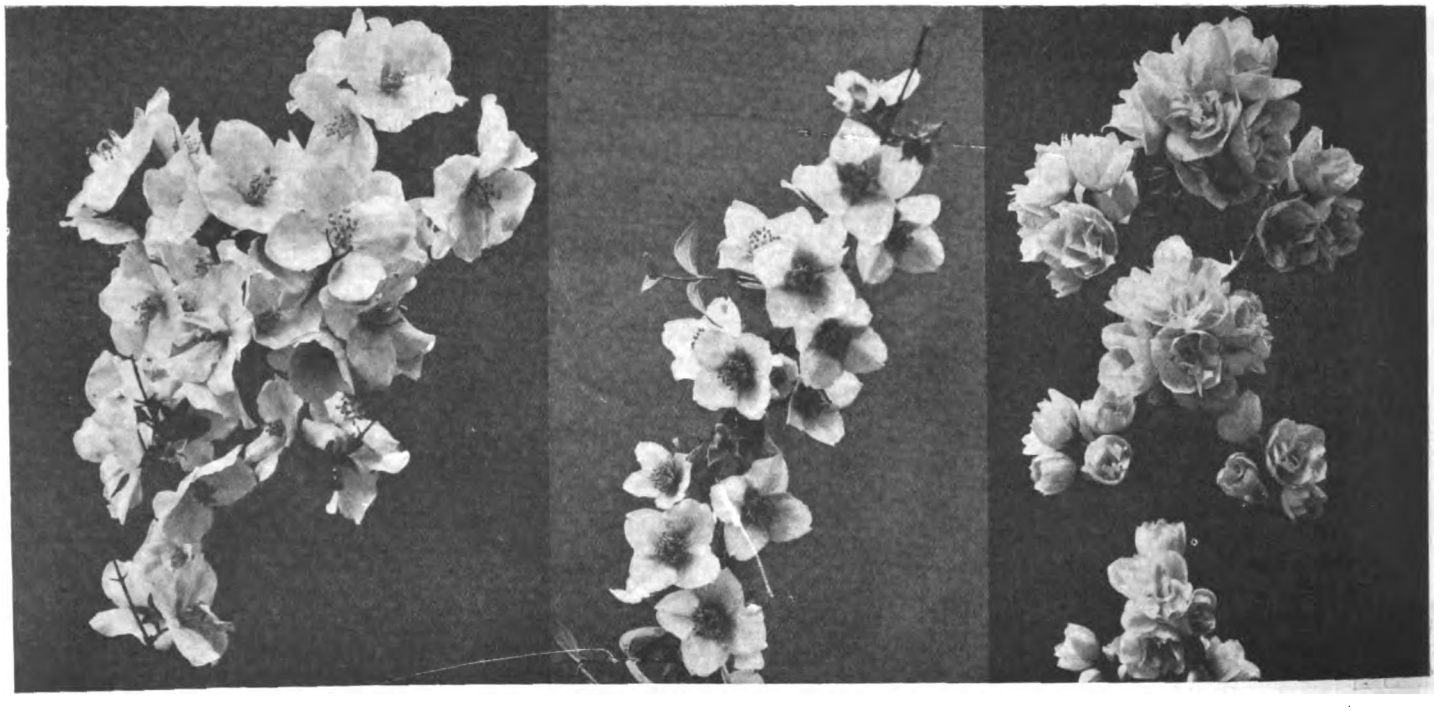
They grow and flower best in open sunny positions, but do quite satisfactorily in moderately sunny situations and on north borders, if they get plenty of light. In addition, they are exceptionally free-rooting shrubs with an abundance of fibrous roots. Hence with ordinary care they transplant readily and safely at any time between about mid-October and the end of March, when the weather is open and the ground in workable condition. Should opportunity permit, plant during the first six weeks of this period.

PRUNING.

Pruning generally implies the shortening of certain of the shoots. In the case of the mock oranges thinning is a better word to use. To shorten the growths might mean the removal of a fair proportion of the best flowering wood for next year. The best time for thinning the growths is immediately after flowering. Keep the bushes open and well balanced by cutting out the oldest stems, right to the ground level if need be. Remove old flowering wood on which there is no new growth, and cut out thin weak twigs where crowded.

With some of the dwarf-growing hybrids, such as Lemoinei erectus and purpureo-maculatus, a system of liberal annual pruning immediately after flowering can be practised with very good results. As soon as the blooms shatter, the flowering branches are cut out to the base or within a few inches of the ground. This induces the production, almos at once, of vigorous young growths which by autumn may be 3ft. or more in height, promising a wealth of blossoms for the following year. Whatever thinning or pruning is done to large and small bushes of mock oranges, the main endeavour should be the encouragement of healthy new growths, as it is from these we must look for the best of next season's flowers.

Mulching with well rotted manure is very helpful to the bushes: in fact, when the intensive system of pruning is practised it is an important part of their cultivation. The mulch can be applied in early spring, or after flowering when the pruning is done. The latter is the more beneficial, especially if the weather is dry; but in some gardens objection is raised to the smell of manure when the beds and borders are at their best in summer.



P. VOIE LACTEE. P. PURPUREO-MACULATUS. P. VIRGINAL.

THREE OF THE FINEST VARIETIES OF MOCK ORANGES.

In height they vary from about 3ft. up to 18ft. or 20ft., while old specimen bushes may be nearly or quite as much in diameter. Here, then, is a wealth of hardy flowering shrubs, the true value of which is fully appreciated in very few gardens. There is a liberal choice in variety for large and small gardens. M. Lemoine of Nancy, when he crossed P. microphyllus and P. coronarius about 1883, had probably no idea that his first hybrid, P. Lemoinei, and the upright form, var. erectus, were the beginning of a wonderful race of hybrid garden shrubs. Excepting the rose and the rhododendron, I can think of no hardy shrub exhibiting to a greater degree the skill of the plant breeder. Another milestone was passed when purpureo-maculatus was introduced by

Digitized by Google

M. Lemoine about 1904. By using P. Coulteri as one of the parents the rich purple blotches at the base of the petals in this species were obtained in some of the hybrids. Thus to-day we have not only the choice of tall, medium and dwarf growing shrubs, but there are sorts with small, medium and large blossoms up to 2ins. across, with single, semi-double and very double flowers. The predominant colour is, of course, white, but this varies from snow white to cream, some with showy rich yellow stamens. We have also to-day an interesting race with the purple blotch represented by Belle Etoile, Bicolore, Etoile Rose, Fantaisie and Sybille.

The persistency of flowering year after year, and the prolific abundance of the blossoms is not the least noteworthy characteristic of the mock oranges. As fragrant hardy shrubs the philadelphuses stand alone, the powerful scent of the dwarf P. microphyllus and its numerous hybrids being exceptional.

During June and July the beautiful flowers and strong fragrance are valuable assets in the pleasure grounds, in small or large groups in shrubbery borders, and planted in masses in the landscape. Single specimens and beds of the dwarf bushy sorts are useful lawn subjects. For small beds plant P. microphyllus and P. Lemoinei erectus; in large beds Virginal and Voie Lactee are particularly effective.

THE LATE-FLOWERING PHILADELPHUS GRANDIFLORUS.

THE SPECIES.

In the recently published Kew Hand List of Trees and Shrubs the names of twenty-eight species and several geographical varieties are given. As cultivated at Kew these exhibit a very interesting race of hardy flowering shrubs. With such a wealth of beautiful hybrids, however, from which to select for extensive garden planting, only a few of the species are sufficiently distinct and of outstanding merit for general use. These are mostly of tall, robust habit, the notable exception being P. microphyllus, a dwarf bushy shrub from Colorado, 2½ft. to 3ft. in height, with small leaves, and powerfully fragrant small white blossoms produced in profusion during June.

P. coronarius is the common mock orange of gardens, a good-natured shrub up to about 12ft. high producing in early June a profusion of fragrant creamy white blossoms. P. grandiflorus is a large bush up to 12ft. or 15ft. high, notable for its large 2in. wide pure white and scentless blossoms. It is a native of the south-eastern United States. P. Lewisii, a species from western North America, is one of the most floriferous of the taller mock oranges. Mature bushes up to 12ft. or more in height are gracefully semi-pendent in habit, covered at the end of June and in early July with white blossoms. P. insignis has cup-shaped white flowers freely borne in large panicles of twenty or more blossoms, a vigorous bush up to 12ft. or more in height. It is a native of western North America. P. Wilsonii, a new species from Szechuan, China, is a useful addition with pure white flowers.

SINGLE-FLOWERED VARIETIES: *Avalanche*, large pure white flowers, bushes 5ft. to 6ft. high; *Belle Etoile*, milk white tinted pink in centre; *Bicolore*, white, purple blotches at base of petals; *Coupe d'Argent*, large sweetly scented pure white flowers; *Etoile Rose*, small foliage, dainty white flowers, with rosy purple central blotches; *Fantaisie*, profuse-flowering, medium size white blossoms with pale rose centres; *Lemoinei erectus*, one of the first hybrids and still indispensable for bedding; *Mont Blanc*, a notably fragrant bush some 5ft. high, upright in growth; *Norma*, large pure white flowers; *Nuce Blanche*, snow white; *Œil de Pourpre*, one of the best sorts with dark purple centre; *Purpureo-maculatus*, the first hybrid with purplish rose centre; *Voie Lactee*, large round snow white blossoms.

DOUBLE-FLOWERED VARIETIES: *Argentine*, large pure white blossoms with imbricate petals; *Banniere*, semi-double flowers which suggest small gardenias; *Boule d'Argent*, masses of snowy white blossoms; *Bouquet Blanc*, double and semi-double flowers in clusters; *Conquete*, long flexible shoots clothed with pure white fragrant blossoms; *Dame Blanche*, semi-double creamy white flowers; *Girandole*, large clusters of double white blossoms; *Glacier*, snowy white, stout erect grower; *Manteau d'Hermine*, dwarf, compact growth, useful front row shrub; *Mere de Glace*, large white rose-shaped blossoms; *Rosace*, arching branches white flowers, deliciously fragrant; *Virginal*, immense pure white flowers, the best double-flowered mock orange.

For a small garden, my choice of six mock oranges would be: Virginal, Voie Lactee, microphyllus, Lemoinei erectus, Œil de Pourpre and Argentine. If there is space at the back of the shrubbery border for a tall bush plant, P. Lewisii. A. O.

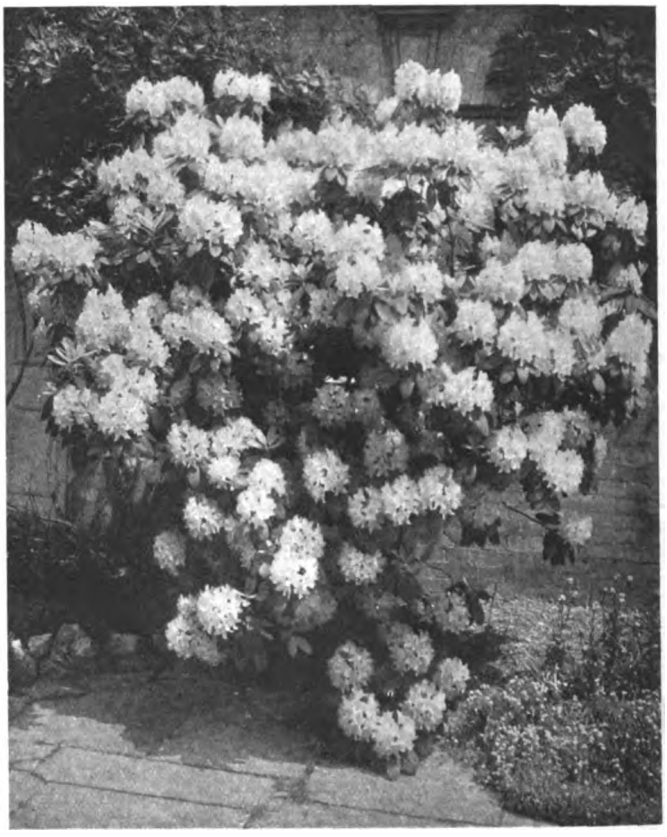
RHODODENDRONS FOR EFFECT

A KNOWLEDGE OF THEIR REQUIREMENTS IS A GREAT HELP IN THE EFFECTIVE USE OF THESE INVALUABLE SHRUBS.

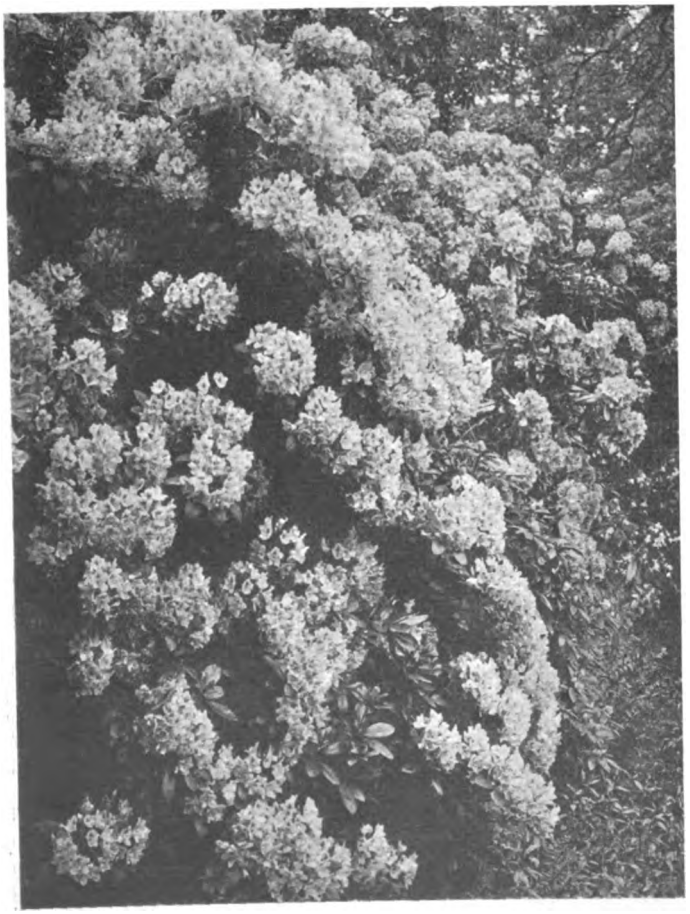
ALTHOUGH the majority of rhododendrons that one sees in gardens are easily grown, yet there are few plants that respond so freely and produce their maximum effect when a little time and trouble are taken over their situation and cultivation. Rhododendrons will cling to life even if planted in the most unsuitable places, but even the hardiest likes some consideration if it is to flower year after year. How often is it decided to plant rhododendrons in some exposed position in the garden because the gardener or owner cannot think of anything else suitable. The argument is always the same. They are hardy and they are evergreen; they produce flowers, so they are better than bays or laurels. This is the wrong way to consider even the common R. ponticum. They should be looked upon first and last as flowering shrubs, and as such they should be planted and tended so as to give the maximum effect.

Everybody knows the conditions suitable for rhododendrons—absence of lime in the soil, plenty of humus, good drainage, shelter from wind and a certain amount of shade, varying according to the species or hybrid to be planted, and so on. There are, however, other considerations that have to be thought of, if they are to produce their blooms to the best effect.

A number of people consider what are called hardy hybrids as desirable subjects for planting in beds. This is usually a mistake, for beds are often made without a thought about surroundings, and rhododendrons, more than any other shrubs, require a background to show off their wares. Not only this, but beds, of their nature, are usually placed in sunny positions, and, however hardy the hybrid may be, there are few that do not lose their colour quickly if planted in full sun. It is often necessary to fill a bed with shrubs, particularly at the approach to a house, but in my opinion azaleas are better than evergreen rhododendrons for this purpose. If some evergreens are preferred, the azaleas can be mixed with Kalmia latifolia. They go excellently in harness together.



THE FINE RHODODENDRON CYNTHIA IN A TUB.



RHODODENDRONS IN THE MASS

SPECIMEN RHODODENDRONS.

Many a sheltered corner of the garden can be improved by one specimen rhododendron which grows by itself and is not crowded by other shrubs. Naturally, in this case a certain amount of care is necessary in order that it may look its best year after year. It will have to be mulched more frequently, so that it may absorb enough food to sustain its yearly blooms; while dead-heading must be seen to if it is to be uniformly floriferous and keep its shape. Probably the best rhododendrons for a specimen plant in an ordinary garden are the magnificent Pink Pearl, which still retains its well earned popularity; its near relative, Cynthia—there is little to choose between the two: the flowers in Pink Pearl are deeper in shade; Loder's White, with large trusses of the palest pink fading to pure white. Reds and crimsons should be avoided if the background is dark, unless the sun definitely strikes them and lights up the flowers. Among the best are two of the newer hybrids—Earl of Athlone, a vivid deep crimson that is particularly floriferous, and Britannia, lighter in colour but quicker growing. Two old Himalayan species are also magnificent—Thomsoni, with vivid scarlet bells, and Roylei, with coppery-crimson tubes. One of the accompanying illustrations shows a fine old specimen of the latter in a garden in Sussex. Both take longer to flower than the hybrids.

RHODODENDRONS IN CLUMPS.

Many gardens have fine clumps of old hybrid rhododendrons as among their most prized possessions. These are always better planted in banks than in circles, for in time to come, when they grow large, it is practically impossible to get into the inside of a circle to deadhead or remove old wood. For the first few years it will be necessary to mulch them well, but once they have grown to some size they will form their own mulch. In favourable districts, when the plants are to

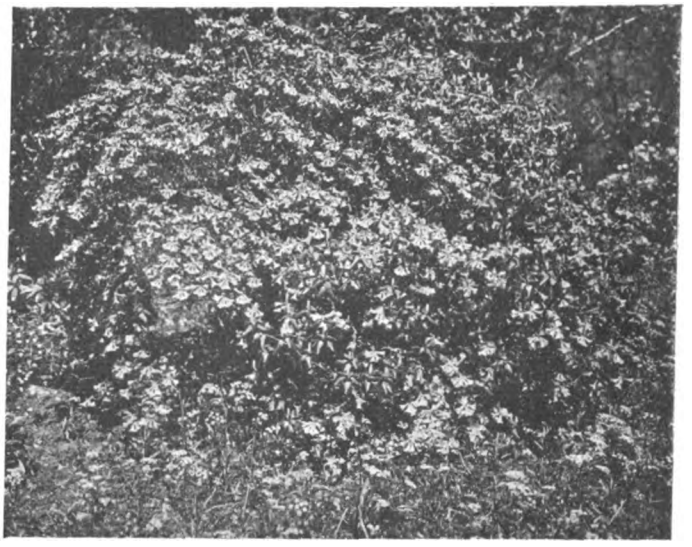
Digitized by Google

be allowed to grow to full size the choice of colours must be made with some care, for many fine clumps are spoiled by having one or two plants which clash horribly and so spoil the general effect. Whatever hybrids are chosen, they should not be those which are heavily blotched or speckled. The number of rhododendron hybrids suitable for massed planting, so that in time they will form a thicket, is legion. Mme. B. de Bruin (crimson), E. C. Stirling (white), Doncaster (a good deep crimson), Corona (various shades of pink), Duchess of Portland (white), Lady Eleanor Cathcart (rose with chocolate blotch), are all excellent. It must be remembered that, however tiresome it may be, deadheading always improves a rhododendron and increases its floriferousness.

Although many of the newer species are not suited for massed planting, yet there is one section, the triflorum, which is excellent for this purpose and should be more often seen in even the smallest garden. Yunnanense (pink), ambiguum (yellow), Augustinii (lilac blue), chartophyllum præcox (white) are all admirable plants that are generally found throughout the trade. They never grow very tall, are graceful in appearance, are among the most floriferous of all species, grow quickly and flower young. Of all species they are undoubtedly the most satisfactory for the average garden. They should be planted close—2–3ft. apart—and allowed to form a thicket, where year after year they will thrive and bloom with added vigour.

One of the illustrations shows a magnificent specimen of Cynthia in a tub, and this is a method of showing off their beauty that is worth trying, provided that you have a fair number of plants. The plant is lifted early in the year before the flower buds show signs of bursting, and after blooming is replanted again. I say, when there are a fair number of plants, for the plant is not improved by potting it in a tub and is often checked for a year; but for a veranda or a terrace there are few things so lovely as a rhododendron covered in a mass of bloom.

E. H. M. C.



AN OLD PLANT OF RHODODENDRON ROYLEI.

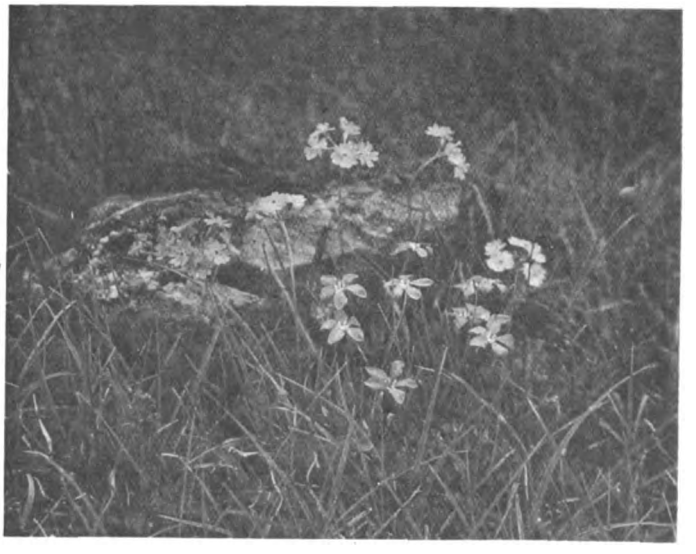
ALPINE BOGS

THE word bog has a sinister ring with us, it brings a picture before one's eyes of horses, huntsmen and hounds being slowly engulfed in a slimy morass, or perhaps a rash sportsman with a gun jumping from tuft to tuft, while the whole surface wobbles like a jelly under him. These sort of places I avoid, but the alpine bogs that hold my interest are lovely things, those where, at the high levels of 6,000 to 10,000ft. snow water rests awhile in its downward rush. Here we find treasures of the first order, orchis, primula, gentian, pinguicula and a host of others. Of orchis we find O. latifolia, with mottled leaves and sturdy spikes of speckled purple; Chamæorchis alpina, rather dull in flower, but an intrepid climber; also Gymnadenia conopsea, the gnat orchis, with spikes of smoky magenta flowers which sit on their stalks looking rather like little parrots with long tails. Nigritella angustifolia, the vanilla orchis, best of all terrestrial orchids, comes down to the edge of the bog and looks at it, but does not like getting its feet wet. Primula farinosa grows here in quantity, in fact, it is the predominant feature. I remember an alpine bog I saw a while ago twice the size of a polo ground, which was aflush with mauve P. farinosa, countless millions of flower heads. I always think there is something particularly dainty about this plant, with its powdered leaves and delicate flowers—it is distinctly feminine. In contrast to it, and close by, grows Bartsia alpina, a robber in brown and purple which, too lazy to make its own living, prefers to fasten on to the roots of its neighbours and live on the nourishment they gather.

Gentiana asclepiadea, the willow gentian, is here and there in patches, a giant among pygmies, for it stands quite 18ins. high and looks much like a Solomon's seal, but instead of small white flowers, it carries fine blue trumpets in pairs along the stem. The plant flowers late, after most of the others are over, and it is a puzzle to me how it ever ripens seed, for almost before its flowers are withered the autumn comes down on it with its blanket of snow. I suppose it must go on with the good work after it has gone to bed for the winter, and with the melting snow the seed is scattered.

A bright spot in the bog is Gentiana bavarica. This must be seen on a sunny day or its petals will be shut, but in sunshine they are dazzling blue—not more vivid than G. verna, because I hold that no blue can outrival it, but darker and quite as brilliant, which is the highest praise.

Of dwarf willows there is ample selection in the Alps, and most of them find their way to the bogs. They are attractive in spite of having no showy flowers to advertise them. It is my ambition some day to have a big collection of them. I am on the way to it already, and I find the more species one gets, the more their fascination seems to grow on one. They are fiends to put names to, because a new plant sometimes needs a season's observation before it will graciously display all the characteristics that go to determine its species. One of the most common in high bogs is Salix herbacea, which creeps flat on the ground and makes broad mats of woody turf. Salix cæsia, the alpine grey willow, is taller, about 3ft. high and grows where the water trickles. If one brushes its branches aside and looks at the ground beneath, one will often find a drift of Pyrola rotundifolia, like lilies of the valley. For those who would cultivate pyrola at home, my advice is, "Don't," It nearly always disappoints one. I have tried P. rotundifolia, P. secunda and P. uniflora, and all that remain unto me are the graves thereof. This is not quite correct—there



PRIMULA FARINOSA IN ASSOCIATION WITH GENTIANA BAVARICA IN AN ALPINE BOG AT SEVEN THOUSAND FEET.

Digitized by Google

is one plant of P. secunda which has remained clothed in a single leaf for two years, but it has got so dirty that it must be dead by now; and I have some plants of P. rotundifolia in peaty sand in a frame, they have demanded such continual attention in opening and shutting their sunshades that I am tired of them.

But to come back to our bog. In the turf just outside the willows there is Parnassia palustris in quantity. This is a plant that always seems to satisfy the eye, the flowers are white with grey pencilling and the whole poise of the plant is graceful in the extreme. Pinguiculas grow close by the water in colonies, with funny little flat rosettes of sticky leaves spread to catch the gnats which they eat, but in spite of this nasty habit, they are dainty. The flowers rise on 3in. stalks and look like violets, hence the popular name of bog violets. The two species common are P. alpina, small and white, and P. vulgaris, a larger plant and purple. Both these are natives in this country, but they are rare except in hilly districts. There is another little friend in the bog which I like very much, Eriophorum Scheuchzeri, a cotton grass, not the E. angustifolium of the lower bogs, with its waving plumes; this is pretty, but the one I love is a little tufted chap like a small rabbit's tail on a thin wire 12ins. high. He comes right down to the water and likes to paddle with his feet well in it—and here he stands affable, erect, and if a wind blows he waves a welcome to you, "How-d'ye-do, must be darned hot down that valley where you come from," and, of course, you feel welcome at once.

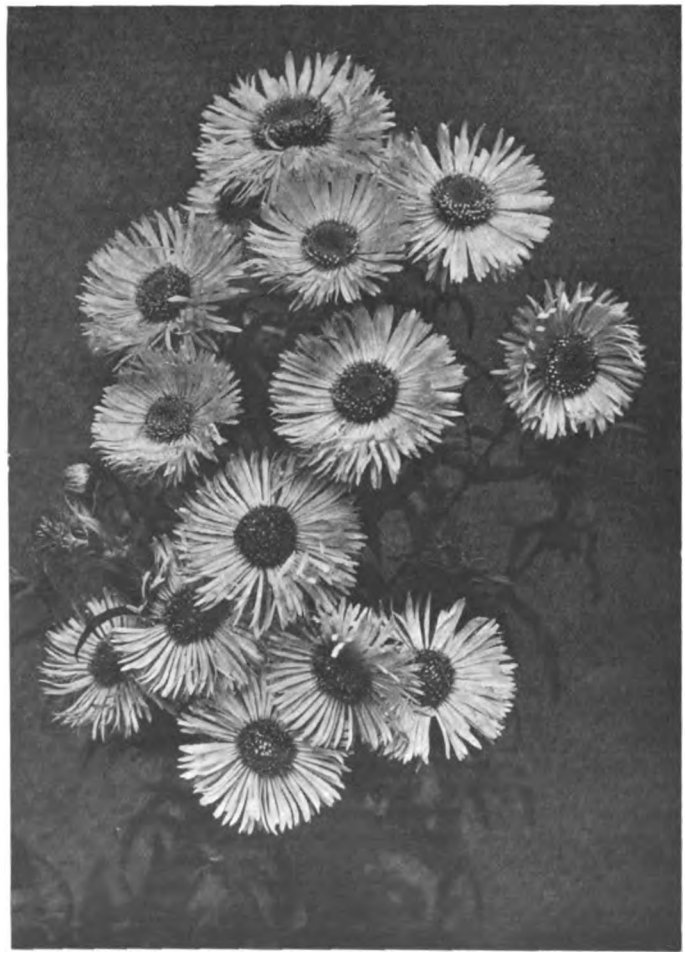
A. GAVIN JONES.

MICHAELMAS DAISIES—III

I HAVE been trying to make out when the name Michaelmas Daisy came into general use, and so far I have been unable to trace it beyond the 'fifties of last century. I am rather inclined to think that this may be the time when the old name starwort began to drop out of ordinary usage, as the newer name probably only gained a foothold when the family became more and more important occupants of our gardens. The time-shed must have been between 1840 and 1860. There is no mention of either China asters or starworts in Glenny's second edition of his "Properties of Flowers and Plants" (1859), which fact speaks volumes. It is of particular interest this late season to record that I have come across a suggestion that Christmas Daisies might be a good name!! I should have thought Martinmas would have overdone it, even in a very late year. But I must pass on to the immediate purpose of this "thirdly and lastly." It is to try to pick out from "The Rest" (that is all but the Amelluses and Novi Belgiis), some of the best. Compared with the Novi Belgii, the Novæ-Angliæ are a very small crowd. I doubt if there are many more than a baker's dozen in commerce, whereas, where is the man who will venture to make a guess at the number of the Novi Belgii? There are two big flies in the Novæ-Angliæ ointment. Many varieties keep closed in dull weather, and many will shut up when cut. Barr's Pink, a recent introduction, is free from these failings, and so is the richer and deeper-toned Miss Kate Broomhead. Personally, after the Amellus and Novi Belgii, I like the cordifolius section the best. How is it that I cannot find that truly magnificent variety, Edwin Beckett, in a single catalogue that has come this year? I bought it in the ordinary way. What has happened? It grows 5ft. high. It has fine big pale mauve flowers. It has a delightful free and easy habit. I cannot give it higher praise than to say, "it is as good as a Novi Belgii." After Edwin Beckett come Comeliness (an early flowerer), and Little Bo-Peep (a late flowerer). These two were raised at Aldenham, and I can hardly believe they have been allowed to remain there. "Full many a flower is born to blush unseen." Are these among them? And yet I know keen and discerning eyes must have seen them. Cheek-by-jowl with Ideal, Little Bo-Peep always seems to me to be the best.

I do not wonder that everyone lists the pretty little ericoides Delight. Among the white-flowered none can touch it. It is one of the earliest to bloom and does not grow more than about 2½ft. high. Twilight is my late-flowering favourite. It is so very white in a mass. Rosy is a pretty little pink variety, but I am not over keen about coloured ones; nor about the little vimineus type. These last are not sufficiently effective in a garden. Last year a kind neighbour gave me a very light looking variety which I am told is the white form of turbinellus. At all events, it is a striking plant, quite unlike any other in my collection. Nicholson in his "Dictionary of Gardening," calls it "A very desirable species." So it is. Its flowers look "all on wires." The pedicels are so thin and long, and the panicles themselves so sparsely set with branches. It makes a good show in the garden, but perhaps it is more useful for cutting, as fully developed sprays are just the thing for using in vases to give lightness to the almost rod-like inflorescences of Belgian Queen or White Climax. I began a bit off the line and I am ending in the same manner, by introducing two plants which ought not to be mentioned here. One is densus—or, to give it its full name, Novi Belgii densus—a low growing variety, which need not be staked, and which, I think, belongs to the era when it was considered the proper thing to give Latin names to garden varieties. Very likely it was in existence about 1900. I believe it is still catalogued by Mr. Amos Perry. Its utility was brought before me in an unmistakable manner when I visited Marbury Hall, near Whitchurch, Salop, this autumn. It is a favourite with Mrs. Poole and it was in evidence everywhere. The other interloper is the so-called yellow Michaelmas daisy, often listed when placed among them as "hybridus luteus." I fear it is a cuckoo. It is really a solidago—Solidago missouriensis, I am told, is its proper name. Anyhow, it is an exceedingly taking little fellow, with small canary-coloured flowers borne on stems of 4ft. high. It also makes a good cushion plant in vases with three or four spikes of a yellow Gladiolus primulinus like Souvenir, coming through it.

JOSEPH JACOB.



BARR'S PINK, A NOVÆ-ANGLIÆ OF EXCELLENT FORM.

Digitized by Google

THE SOUTH AFRICAN WAND FLOWERS

FOR the gardening enthusiast, who likes to grow something uncommon and at the same time beautiful, the subject of this short article can be recommended. The wand flowers—or, to give them their proper name, Dierama pulcherrimum—are peculiarly graceful, the slender flower stems growing to a height of from 5ft. to 6ft., bearing beautiful bell-like flowers in varying shades of pink, deep red and claret. Though they may not be hardy in exposed situations, they certainly merit a trial, and for the possessor of a large border nothing more beautiful could be recommended. In the following notes I want to draw attention to a few of the splendid seedlings that have been named and recently placed on the market by the Donard Nursery Company, Newcastle, County Down.

Dierama pulcherrimum alba. — This beautiful white variety was one of the first to be selected and exhibited, and it obtained a well deserved award of merit from the R.H.S. In the early stages the flowers are tinged with pink, but this disappears as the blooms develop. It is one of the smaller-growing sorts and should certainly be included in a trial order.

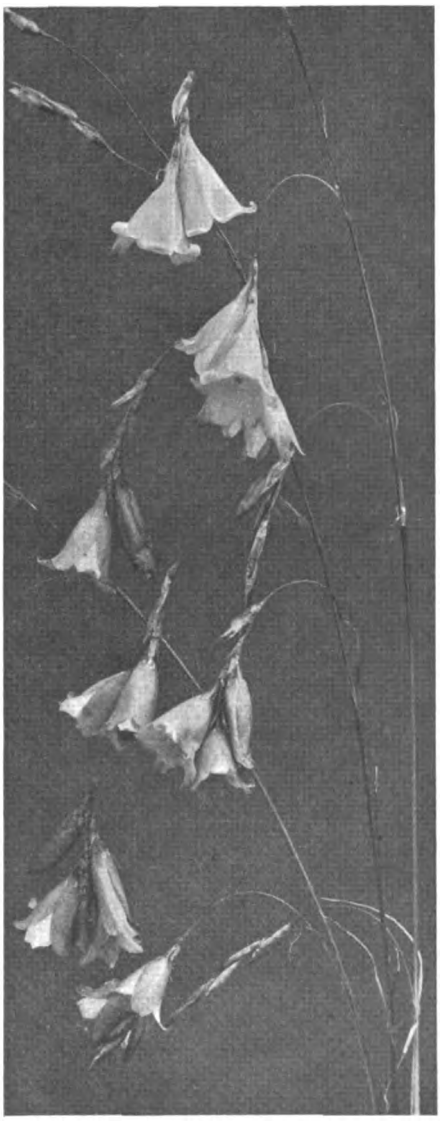
Heron.—This is, perhaps, my favourite to date, and its glorious rich wine red flowers carried on tall waving stems are undeniably striking and beautiful. The award of merit of the R.H.S. has also been obtained for this seedling, and I predict for it a great future.

Curlew.—This is another deep-coloured dierama, similar in shade but with more of a purple hue—bright reddish purple is the catalogue description, and it certainly conveys a very accurate idea of the colour.

Kingfisher.—This prettily named variety is probably about the best of the pinks and the colour is a very beautiful one. It got a unanimous award of merit at the R.H.S. on July 8th, 1924, and is about the largest flowered of the present range of seedlings.

Windhover. — Another attractively named sort and one that is robust and very free-flowering. The colour is a deep lilac-rose, and should prove very popular when better known.

Will o' the Wisp.—Appropriately named and of a pale shade of pink, the individual flowers are small but rather more freely carried than in the case of some of the other varieties.



WAND FLOWERS, GRACEFUL AND BELL-LIKE.

Magic Wand.—A delightful variety of a pretty art shade of pastel or lavender pink. This is another vigorous seedling, while the individual bells are very open in shape, which helps to give it a distinctive appearance.

Heatherbell.—One of the less expensive sorts, but nevertheless very charming and well worth a place in this select company. The flowers are a pretty shade of pink, flushed deep rose and are very effective when in full bloom.

This concludes the list of varieties to date, but there are other seedlings of great promise which, when placed upon the market, should help to make this uncommon and graceful race of plants more popular than is the case at present.

I will not attempt any cultural notes, for my experience of growing them is very limited; but, judging from their vigour of growth and the freedom with which they produce their flowers during July and August in the North of Ireland, where I have had many opportunities of studying them, they should, with ordinary care and attention, give satisfactory results in all but exposed districts.

In conclusion, I would suggest the following four varieties as about the choicest of those mentioned, and, in my opinion, they would make a good start for a collection, namely, (1) Kingfisher, (2) Heron, (3) Windhover and (4) Alba.

Of course, as is the case in selecting varieties in all other types of plants, tastes differ; but, after all, that is one of the charms of gardening, and it would indeed be dull and uninteresting if we all made the same roses, sweet peas, etc., our favourites.

I only hope that some readers of THE GARDEN may be encouraged to try their hand, and, if so, that success and much pleasure in the possession of an uncommon and at the same time delightful flower may result.

I should perhaps add that dieramas show to best advantage when grown in bold clumps or groups, and, in my opinion, it would be better to order, say, six or more of one variety than to try to include all the sorts mentioned. A very good mixed collection of unnamed seedlings, however, is offered, and this should appeal to those who like variety and are not particular about growing special sorts which are, naturally, rather more expensive. CECIL M. BAILEY.

NOTES OF THE WEEK

HELENIUMS.

THESE well known summer and autumn flowering herbaceous plants have long been grown to add to the brightness of the border with their gorgeous masses of yellow and golden brown flowers. With the advent of new and improved varieties this race of plants is still further increasing in popular esteem. They bloom from early summer to autumn until the frosts arrive.

For practical purposes they can be divided into two groups: those varieties that begin to flower in early summer and those that are purely autumn flowering. The earlier-flowering varieties are dwarfer in habit than those coming into bloom in the autumn, the former, being, as a rule, some 2ft. or 3ft. in height and the latter from 4ft. to 6ft. tall.

They are very accommodating plants and will produce excellent results in any reasonably good garden soil. Propagation is readily effected by division, shoots from plants divided in the autumn or spring making a good flowering clump the next season. Personally I find it a good plan to split up the old plants every other year when the herbaceous border is gone over and replant the best of the pieces some little distance apart. Not only are the flowers then of good quality, but, a point I consider to be of some importance, the stems produced are stronger, and staking is thereby reduced to a minimum. Those dwarf sorts that are worth growing should not require staking if this plan is adopted. Most of the taller-growing sorts need some assistance in this direction, however, where the situation is at all exposed, in order to withstand the heavy winds of autumn which have such a disastrous effect on plants top-heavy with flowers loaded with moisture.

If the earlier-flowering sorts are cut back and the spent flowers removed, they will go on flowering well into the autumn.

Of the dwarf sorts, Crimson Beauty is one of the finest yet raised; the flowers, which are of a brownish crimson colour, shading off into old gold as the season

Digitized by Google

advances, are borne on stout, branching stems some 2ft. in height. This is a comparatively new introduction and is a valuable acquisition. It stands up particularly well against the onslaughts of wind and rain, far better than any other variety.

Another good dwarf sort is H. Bigelovii; the flowers of this variety are of a golden yellow colour. It is a very effective free-flowering sort of compact habit.

A particularly pleasing variety is July Sun. It is slightly taller than the two foregoing, but the stems are stout and erect. The individual flowers are bright yellow in colour, with dark centre.

Of the taller heleniums, Riverton Gem is a very good type. The flowers are of a terra-cotta tone, suffused with old gold. It is a good, robust grower, and one of the best sorts to grow. It is some 4ft. tall.

Where a rich warm tone is desired a very useful sort is H. autumnale rubrum. The flowers are deep crimson mahogany in colour, frequently shaded old gold. The flowers are of good size and the plant is about 4ft. tall.

Gartensonne is a good sturdy grower with strong stems, about 5ft. in height. The flowers are golden yellow in colour with velvety brown centres.—HOWARD H. CRANE.

THE TRESCO ABBEY GARDENS.

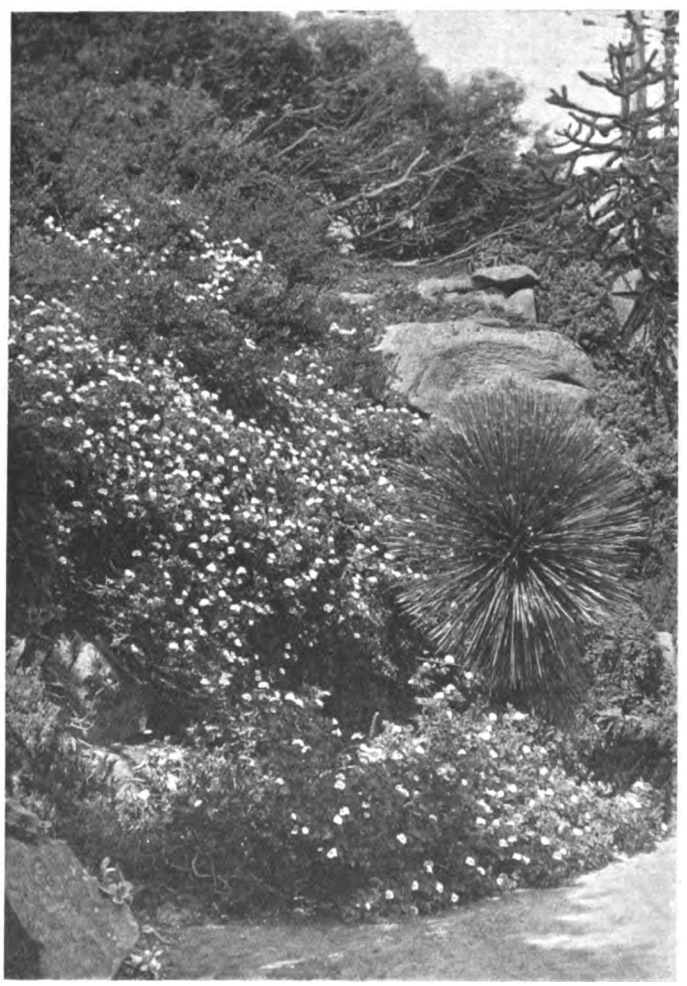
THE conditions obtaining on the Scilly Isles are not more favourable to plant growth than in other parts of the country, with the single exception of the mild winters experienced. Otherwise, we on the mainland have great advantages, in many ways. In the first place, the soil of Tresco is of a light, peaty nature, so shallow that big trees cannot securely anchor themselves. Again, very violent winds are experienced, such winds as we rarely encounter, and which tax to the utmost the skill of the cultivator in the provision of shelter. This point is impressed on my mind by a remark made by Major Dorrien-Smith. Pointing out a very pretty view, over a lake, through a break in the trees, he remarked, "Very pretty, but I do not like to see it because such a break can let the wind in."

The gardener, visiting the Scillies for the first time, experiences the greatest disappointment as he sails past the many rocky islands, bearing no vegetation but low, stunted gorse. As scenery it is grand, but interesting plant growth was expected. The fertile island of St. Mary's does not look exciting. One can see its slopes marked out into square fields, which grow early potatoes and bulbous flowers, but not a tree is visible. Nothing is, apparently, of greater stature than an arum.

As soon as Tresco island is sighted, however, hope again revives, for one catches a glimpse of the Abbey on the outskirts of an extensive wood, which stretches over the top of the slope. It is this wood that has made Tresco gardens possible, for it shelters from the rough winds all the exotics growing there. The wood is not native, but was made by planting Cupressus macrocarpa and Pinus insignis.

It is difficult to say what is the outstanding feature of Tresco gardens. Going through the rockery, with its large collection of mesembryanthemums, aloes and agaves, one would say succulents are the strong point. Then a walk through the collection of trees, shrubs and palms would cause a change of mind. Or a tour into the wood where gaps and clearings are filled with rhododendrons, acacias and eucalyptus in great variety, with large patches of arums in full flower in the boggy places causes one to consider whether any particular class of plants has been specialised in; apparently all phases of gardening and plant life are studied and cared for.

To give a list of the many interesting plants seen would probably interest few readers, but to mention that such plants and trees as Howea palms, Araucaria excelsa, Cinnamomum Camphora, Cordyline australis, Metrosideros spp., Phœnix canariensis, Aloe spp., Dracæna Draco, Fuchsia spp., Agave spp. and tree ferns are to be seen as large, full grown specimens, will give an idea of the vegetation. Of Cape pelargoniums, mesembryanthemums, eucalyptus and acacias, innumerable species are grown. Of particular interest to one who has seen them growing in their native habitat were Lobelia Gibberroa, the African tree lobelia, and Sparmannia africana. Both are flourishing at Tresco in a manner quite unexpected. It really is difficult to say what will, or will not, grow there. The Nyassaland cedar, Widdringtonia Whytei, is represented by quite a fine specimen. Attempts to grow this tree in Natal were not nearly so successful and Pietermaritzburg Botanic Gardens cannot show such a fine tree as Tresco. After seeing Sparmannia africana and Phœnix canariensis both growing as luxuriantly as they do in their native home, it would appear as if most plants are worth trying.



A CORNER IN THE ROCKERY, WITH PELARGONIUMS IN FLOWER, AT TRESCO ABBEY GARDENS.

My visit, in May, was too early to see the gardens in their greatest glory. The metrosideros, crassulas, mesembryanthemums, tigridias and hosts of other plants were not in full flower, but the gardens were still gay with large clumps of pelargoniums, sedums, cinerarias, arctotis, watsonia, lithospermum, bomaria, habrothamnus and many another plant and shrub not to be seen in the open air in this country.

A noteworthy plant, not in Tresco gardens, but on the estate, is Bougainvillea Sanderiana. It covers the front of a cottage, and, I was informed, flowers very finely. It certainly made growths several feet long last year. It is probably the only bougainvillea flourishing in the open in northern Europe. It provided another of those surprises of which Tresco seemed so full.

As would be expected of a plant enthusiast such as Major Dorrien-Smith, visitors to the gardens are welcomed, and notices to this effect are posted up on the island. Many will go away from these gardens with grateful thanks to Major Dorrien-Smith for giving them the opportunity of seeing what the Tropics are like, for a very real idea can be obtained there.—E. BROWN.

GERMINATION OF SEEDS OF ARCTOSTAPHYLLOS PUNGENS.

HAVING tried unsuccessfully to raise plants from seed of this shrub in the ordinary way, I took the hint which Mr. Bean gives in his book on "Trees and Shrubs," and dividing the packet of seeds into four equal portions, boiled them for five, fifteen, thirty and sixty seconds respectively, but after twenty months this seed still remains dormant, although it looks quite good. I managed with great difficulty to open one of these seeds and the flesh is still white and firm.

In February of this year I sowed fresh seed again, but placed the pot in a very warm greenhouse, but after six months nothing had happened and needing a pot of similar soil quickly for seed of Gaultheria pyroloides, I placed the pot containing the seeds of Arctostaphyllos in the oven with the idea of killing the moss spores, etc., and forgot all about them until I was reminded almost three hours after. Naturally I thought everything would be killed, seeds included, but I sowed the seed of gaultheria on the top of the well baked soil (after it was cold, of course), and now, after two months, I am rewarded, for both of them are germinating freely.

I do not know what the temperature of the oven was, but I know that a rice pudding was cooked in the compartment above during the time the pot occupied the oven. —B. LEACH, *Headley, Epsom.*

A FINE CLEMATIS.

THE enclosed photograph shows Clematis Fargesii growing in my garden in Perthshire. This species is a native of western Szechuan, growing at an altitude of about 9,000ft. It was collected by Wilson in 1910, and is a strong climber 9ft. to 18ft. high.

This species differs from the others in the group in the inflorescence, which is reduced to one or three large flowers; but the flowers, even when solitary, are always

Digitized by Google

CLEMATIS FARGESII IN PERTHSHIRE.

borne in the distinct peduncles in the axils of the leaves of young branches. This handsome clematis is not common and is always found in the woodlands of its native habitat. The flowers are white, 1½ins. across and very pretty.

This species is quite hardy, more so than C. montana, which with me gets killed during a hard winter. It is an extraordinarily free bloomer, coming into flower in June and continuing till the end of October.—A. HARLEY.

KNIPHOFIAS.

THESE very effective hardy border flowers, formerly known as tritomas and commonly called torch lilies and red-hot pokers, are being planted more extensively every year. From July to November there are three subjects, that, planted singly or in the mass, according to the space available, always appeal to me, namely: Prunus Pissardii, pampas grass and the kniphofia. The rich foliage, the stately plumes and the striking spikes respectively, combine to make a very fine display, which remains effective for a considerable time. But I wish to refer more especially now to the kniphofia. Those who love these flowers and wish to grow them, but do not understand the behaviour of the plants, may think it necessary to plant them during this autumn period. In certain circumstances they may be planted in the autumn, but care should be taken throughout the winter to protect the roots in the loosened soil from severe frosts, by placing a good layer of dry litter around each specimen and close up to the leaves. If the time can be chosen, then do the planting in the spring in duly prepared ground. With some gardeners it is a duty never to be shirked to trim off the outer leaves of plants in the borders in the autumn and early winter time to make all look tidy. In the case of numerous kinds of plants this is a very necessary work, but in that of the kniphofia it is wrong to cut off more of any leaf than, it may be, the dead portion. Retain all the sound foliage possible whether on established or newly-planted specimens.

The best soil for these plants is one well drained and of a light loamy nature, although I have grown them fairly successfully in an almost pure clay, and in this medium the plants bore very highly coloured flowers. Since the early days of the old variety, K. Uvaria, with its scarlet flower spikes, we have had, especially of late, a succession of new sorts from self yellows to buff yellow and scarlet and orange combinations, and the height ranges from 2ft. to 7ft. Thus we see how easy it is to arrange the plants suitably in a border, singly or in clumps or in separate beds. For a small border, rufa, yellow spikes, tipped red; Macowani, orange-scarlet; Goldelse Improved, yellow self; Buttercup, golden yellow self; and Prince of Orange, rich orange flowers, with Empress, red, all under 3ft. in height, will never be out of place. For the back of a large border perhaps multiflora, sulphur and 7ft. high, is the tallest-growing variety, and there are lovely sorts intermediate in height.—G. G.

A REMARKABLE FRUIT.

THE singularly constructed fruit here illustrated is that of a plant called Proboscidea altheifolia, which grows wild in the deserts of northern Peru. The genus is closely related to martynia, two or three species of which are occasionally grown in gardens as annuals. In its younger state the fruit is a kind of spindle-shaped pod with two horns. As it ripens it splits open and these horns become reflexed and curved inwards, thus revealing two smaller, decurved horns in the centre. The horns have sharp, hard points and measure 3ins. to 4ins. in length.

There is no doubt that this remarkable structure is a provision to assist in the dispersal of the seeds of the plant, one of the most elaborate of the various plans nature adopts. The curved horns catch hold of the hairy coats of animals or may even clasp their legs and are thus transported considerable distances before becoming detached—dropping seeds by the way.—W. J. B.

FRUIT OF PROBOSCIDEA ALTHEIFOLIA.

THE DABŒCIAS.

THE Irish, or St. Dabeoc's heath, is an exceedingly beautiful family of dwarf ericaceous shrubs, valuable for planting in quantity where the ground is comparatively free from lime. In nurseries the name of Menziesia polifolia is more often favoured, though according to the rules of priority, the name Dabœcia polifolia is the correct one.

Mature plants form evergreen spreading dwarf shrubs up to 2 feet high with age, and as much or more in diameter. They are among the most floriferous and charming dwarf shrubs we possess, for the season of flowering extends from June to November, with a particularly showy period during August and September.

There are several varieties in addition to the type, which has rosy purple blossoms: alba, pure white; alba globosa, dainty globular white flowers, plants of more upright habit; bicolor, white and purple; and atropurpurea, red-purple flowers and dark foliage.

The dabœcias are readily propagated by seeds, cuttings and layering. It improves the habit of the plants, and they last many more years in good condition, when the old flower spikes and long ends of the previous year's growth are trimmed off with shears early in the year, before new growth begins.

Lawn beds of the Irish or Connemara heath are very effective, but one is inclined to enthuse most in favour of planting in large informal groups on sloping ground in the pleasure grounds, sometimes in colour groups with others in mixture.

The dabœcias are found in a wild state in western Europe (western France, Spain, Portugal, the Azores) and Connemara, Ireland.—A. O.

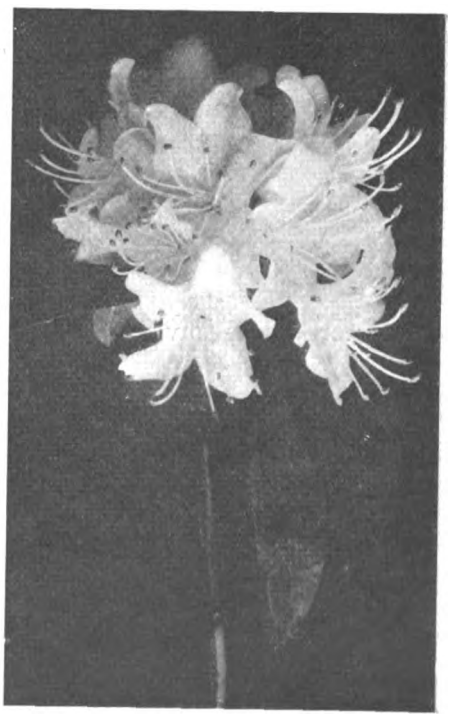
RHODODENDRON HORMOPHORUM.

BALF. F. ET FORREST.*

RHODODENDRON hormophorum is one of the many rhododendrons introduced in recent years from China by Mr. G. Forrest. It is one of the triflorum series which, from a horticultural point of view, may be described in general terms as a dwarf R. yunnanense.

Sir Isaac Bayley Balfour, commenting on the species in the Notes of the Royal Botanic Garden, Edinburgh, says, "It is a plant the habit of which is in consonance with its described habitat—dry stony alpine pastures. Its stem appears to ramify in the soil under the stones, rooting and forming crowns from which short aerial shoots ascend, bare below and producing small tufts of leaves and trusses of flowers at the top. The community of such plants must form a scrub about a foot and a half high after the fashion of old heather on a moor. As a plant of cultivation, R. hormophorum is likely to prove hardy, but does not give evidence of greater or less attractiveness than many others of its Series." This estimate, based on the collectors dried specimens, has proved an accurate one. The plants I have seen in cultivation have a somewhat "leggy" habit. Most of the leaves formed in the preceding year fall before or when flowering commences, with the result that at the time of flowering we have almost bare shoots crowned with flower trusses and short new growths of immature foliage, with, perhaps, a few of the leaves of the preceding year persisting below the flower trusses.

This defoliation notwithstanding, R. hormophorum may prove to be a desirable form



A FLOWER TRUSS OF R. HORMOPHORUM

Digitized by Google

for small gardens and for particular situations if it retains in cultivation the low stature of the wild plant. The flower truss is not inferior to some forms of R. yunnanense, and the flowers individually have the graceful form characteristic of its allies: an open corolla, azalea-like in shape, with protruding and curved stamens and style. The flower colour varies from a light pink to a deeper rose or rose-lavender, and the posterior part of the wide tube is spotted on the inside with olive-brown or maroon dots, after the manner of R. yunnanense.

In the description referred to below* it is pointed out that, apart from dwarfness, the species is distinguished from cognate forms by the whitish disc-like peltate scales about equally distributed on the upper and under surfaces of the leaves, and that the calyx provides a diagnostic mark which is utilised for the name of the species. This mark is the presence of "white peltate scales disposed close-set along the rim of the lobes (of the calyx) forming a white necklace-like band around the base of the corolla." The feature is a minor one, but all the flowers of plants of R. hormophorum that I have examined, flowers of plants in cultivation and those on the Chinese gatherings also, possess this feature. It appears to be a constant and diagnostic mark separating the form R. hormophorum from the typical R. yunnanense.

R. hormophorum was discovered by Mr. G. Forrest in 1918 (Forrest No. 16265) on the Muli Mountains in south-western Szechuan and was again gathered by him in 1921 in the same area (Forrest No. 16816), and also farther south on the mountains east of Yung-ning (Forrest No. 20485) at elevations ranging from 10,000ft. to 12,000ft.

A single plant flowered at the Edinburgh Royal Botanic Garden in 1924 under the Forrest No. 16816. This year, under the same number, a second plant flowered; and at Edinburgh and elsewhere plants have flowered this year under the Forrest No. 20485.

*R. hormophorum, Balf. f. et Forrest, in Notes from the Royal Botanic Garden, Edinburgh, Vol. XII (1920), page 117.—H. F. TAGG.

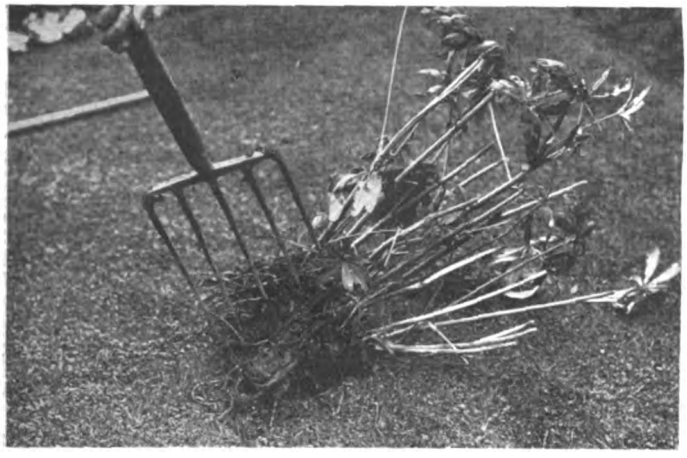
THE PROPAGATION OF HERBACEOUS PLANTS

HARDY herbaceous plants may be propagated in many ways, and at different times of the year. The principal methods employed are by means of seeds, cuttings, layers, offsets, bulbs, tubers, runners and division of the plant or rootstock.

Propagation by means of seeds is the most natural method of increase, and the one by which the majority of plants reproduce their kind more or less true to type, except where the flowers have been subject to cross fertilisation by the pollen of other species. Where exact counterparts of plants cannot be ensured by raising from seeds, there are generally other methods which can be applied: as by the insertion of cuttings, or the division of the plant. The great majority of annuals must, of necessity, be propagated from seeds, as the plants generally die after flowering and ripening their fruits.

The conditions requisite for raising plants from seeds, are the proper ripening of the latter, their careful preservation till they are sown—so as to ensure the retention of all germinative properties—and their insertion in the soil at the proper time under conditions suitable for their development. Some seeds, like those of many of the umbelliferæ, even when perfectly matured, retain their germinative powers for but a comparatively short time; while others, like those of some leguminosæ, kept under favourable conditions, retain their vitality for some years.

One of the chief considerations in sowing is to choose the time so that the young plants shall appear above ground at a season suitable for their after development. Tender annuals that will not stand cold must be sown in a little heat in spring, or outside in April or May. Hardy annuals may be sown outside, where they are to flower, in March, or some do better if sown in the previous September. In the latter case they make good plants before winter, and come into flower earlier than the spring-sown ones. Seeds of plants that are biennial—that is, do not flower until the second year—require sowing before or soon after midsummer, a season favourable for germination, and one which allows the plants to become established before winter. The best method of sowing seeds outside, and the one generally practised, is that of sowing in drills. This affords more convenient opportunities of cleaning and thinning the seedlings than when the seeds are sown broadcast. Under glass, pans or pots may be used, but the drainage must be good, and the soil light and sandy. In sowing seeds care must be taken that they are not covered too deeply. A good rule is that of covering seeds, when sowing, with an amount of soil equal to their own depth. If seeds were very small, and covered deeply with soil, in all probability the plants would perish before reaching the surface. When once the seeds are sown, the soil in the seed pots should never be allowed to get dry. It is a good plan to keep them covered with paper or other covering till the seeds germinate.



THE METHOD OF DIVISION BY MEANS OF A FORK

A CLUMP OF LUPINS DIVIDED AND READY FOR PLANTING.

Propagation by means of cuttings is, perhaps, one of the most useful methods. Nearly all alpine plants can be increased in this way during the summer months. Inserted round the edge of a pot in sandy soil, and kept in a close frame, they soon root. As soon as they are rooted and commence growing, the cuttings can be potted off separately into small pots, kept growing in a close frame for a time and then hardened off gradually. Some cuttings emit roots from almost any part of the stem, while others need a joint or heel, and preparation of an exact nature to ensure the emission of roots.

One of the easiest methods of increase is by means of division of the plant, when it consists of many crowns or growing points. This can be done in the autumn or early spring. The whole plant is taken up, and pulled apart by hand, or with two forks, not cut by a spade. For replanting, select the stronger crowns, which are generally found on the outer edge of the plant. As these divisions are all provided with roots, they soon become established when planted firmly.

Offsets, tubers, bulbs and corms are formed, in some cases, on the stems of the plants which bear them, but more generally about their roots. When they are produced, an easy method of propagation is effected by separating, or lifting them, when the old plants ripen and their tops decay. Tubers admit of being cut into several pieces, each of which will eventually form another plant if it is provided with a good eye or bud. The potato is an example of this, while in the crocus the young corms are formed in quantity round about the old one. These can be

Digitized by Google

Michaelmas Daisies ready for division and re-planting.

The individual portions, which are too large, are here planted too close together.

The correct procedure to follow with portions of small size; each is given ample space.

lifted when ripe, separated and planted out singly in lines in a nursery bed or frame, till they are large enough to plant out in their permanent quarters. Runners, as in the case of the strawberry, provide an easy means of increase. These are lifted, when rooted, and planted out in rows where they are to flower and fruit. Propagation by means of root cuttings can be carried out with many plants, like Anchusa italica, Morisia hypogæa, and many cruciferæ. In the autumn the plants are lifted, when the larger roots are selected and cut into lengths of two or three inches. These are put into sandy soil in pots, or a bed in a cold frame, or even outside. In the spring, buds are developed and fresh roots produced, resulting in good plants which will often produce flowers the following summer.

All cuttings should be selected from healthy plants, and it is very important when inserting, that the base should be placed in contact with the soil. The soil should be made firm round the cutting, as many failures result from loose planting. W. I.

THE PRUNING OF FRUIT TREES

A VERY prevalent but very fallacious idea is that every fruit tree requires pruning annually. Many people would consider it madness to plant a young fruit tree and leave it unpruned; oftentimes the folly lies in pruning it. The general rule is that a fruit tree is better left unpruned the season it is transplanted. The principal branches and strong young growths should be left intact until the roots have had a year in which to establish themselves, while any weak twiggy growths should be removed.

Another frequent error is to suppose that when a young tree makes a great amount of strong young growth the obvious method of checking it and hastening the development of fruit buds is to prune it hard. That is precisely the way to induce an even stronger growth of wood, and hinder instead of help the formation of the desired fruit buds.

A young tree that makes but little growth is the tree that requires the knife, and provided the tree is healthy and comfortable at the root, severe pruning will usually rouse it from its lethargy and start it into satisfactory growth.

Impatience to see a young tree bearing fruit is the greatest stumbling block when the owner of such trees that have been planted a year approaches them with the knife. In all probability many fruit buds have formed on the upper portions of the two year old wood, but, nevertheless, these must be sacrificed for the sake of the future fruit production. Disinclination to heed such advice is strengthened by the knowledge that a friend's trees carried a fine crop the second year after planting, and that even the nurseryman, when he supplied the trees, was strong in his assurance that they would fruit well the second year. Both these contentions may be literally true, but the important fact is that in produing those first fruits the development of the tree is jeopardised in a manner that will be dearly paid for in years to come. The young tree that carries fruit before it has developed the framework of a good, sturdy, well balanced tree must pay the penalty in stunted development and crippled physique.

Much importance attaches to the precise point at which a branch is cut at this first pruning of newly established trees, for bear in mind the object in view is to promote the growth of the permanent and principal main branches. The stereotyped instruction on this point is to cut to an outward-pointing bud. Careful examination of a young branch will reveal the fact that the bud immediately below the outward-pointing bud points directly inward to the centre of the tree, and when, as a result of pruning, this bud produces a shoot, it will have to be removed, to keep the centre of the tree open. That means only one young shoot is preserved, and there is no increase in the number of main branches formed. Further search along the branch to be pruned will discover a point where two buds, quite close together, both point in an outward direction, and if the growth is cut clean immediately above those two buds both will produce shoots, growing outward and in diagonally opposite directions, like the limbs of the letter "V." Thus may the number of main branches be increased to anything up to double their original number. In any later pruning for extension, when the number of branches requires no further multiplication, it will be quite correct to prune to a single outside bud. The varying details of pruning trees of different varieties and varying ages would fill a volume, but in the main it is safe to assume that a slow-growing tree may be severely pruned, and one that makes vigorous growth should be very lightly pruned. It is a good plan, when trees of five or six years of age are still making an abundance of wood, to leave the leaders of all the main branches untouched, shortening back only the lateral growths. In the case of older trees it is more often than not of greater importance to use the saw on crowded branches than to use the knife on young wood, and the trees that have been systematically pruned for a number of years are sooner or later bound to require judicious thinning of overgrown spurs.

The knife is mentioned from force of habit, but, true as it may have been in time past that it was the only tool with which a tree could be properly cut, there is no sound reason to-day why secateurs should not be used so long as they are of the very best quality and modern pattern. The fault of the antiquated patterns of secateurs was that they jammed and bruised the bark and wood; but the best makes to-day have keen, double-cutting edges and can do their work as cleanly and very much quicker than the knife, and there is far less risk of accident in the way of cutting more than was intended.

Many people who make a fairly good job of pruning a bush or standard apple tree are less comfortable when operating on cordons, and he makes a mistake who prunes his plum trees precisely as he prunes his apples. The plum, where it is happy, usually requires very little inducement to make wood; frequently it is more desirable to check the tendency to make too much. To cut back vigorous leading shoots simply induces greater vigour. Open out crowded portions of the tree, but otherwise cut as little as possible until the exuberance tones down. Fruit will usually be borne the sooner for this treatment. The laterals of cordon trained trees should be pinched back in summer; from the latter end of July onwards, doing little and often,

Digitized by Google

rather than making too drastic a reduction of foliage at one time. The winter pruning will then consist of cutting the shortened growths farther back—to growth buds in very young, undeveloped trees, and to plump fruit buds in mature trees. The life of cordons may be considerably prolonged by periodical thinning of crowded fruit spurs, and encouragement of new buds in convenient positions. A final warning may well be to beware of starting to prune while a few leaves still remain upon the tree. This is one of the tasks for which an early start is of no advantage. It is unwise to prune during periods of actual frost; but while trees remain dormant any spell of open weather is the right time for pruning.

A. J. MACSELF.

ANNUALS: AUTUMN SOWN *v.* SPRING SOWN

AN annual is a plant which completes its life-cycle within a year. By common practice "within a year" is interpreted to mean between January and December, but the observant have long since discovered that in the wild state the majority of annuals start their new year immediately after ripening seed.

Nature is very wise, and the cultivator who follows her lead is prudent, and it has been abundantly proved that autumn sown seeds of annuals produce more robust and more prolific plants than those sown in spring.

That statement may require the qualifying remark that the greater success is dependent upon judicious care of the young plants during winter.

Failures occur, but investigation sometimes discovers that neglect allows the seedlings to fall victims to natural enemies, and in other instances, coddling and nursing are carried to an extent that undermines the constitution and stifles the plants into sickness.

Many hardy annuals should be sown in the open, but date of sowing and selection of situation are points of more than trifling importance. It is easily possible to sow too early, especially where the seed bed is on rich soil, which is conducive to soft, sappy growth.

Small seedlings of hard, wiry growth will endure the rigours of winter far better than bigger, softer plants of the same kinds. For the most part outdoor sowing should take place in September, but in some seasons seeds of Shirley poppies, calendulas, sweet alyssum or larkspurs may be sown on a border with a western exposure as late as mid-October and the seedlings, although quite small, survive the winter and make rapid headway in spring.

Late in October hardy annuals may still be sown in frames, but the lights should seldom be closed, and the more air the seedlings are allowed to enjoy on favourable days the sturdier and healthier the plants will be. It is a great mistake, even in winter, to keep hardy annuals in heated pits or greenhouses. When seeds are sown too early the question of pricking out becomes a problem. Often the seedlings become large enough, and being somewhat crowded, appear to require pricking out, but they make fresh root very slowly after disturbance in late autumn, and it is usually wiser to thin crowded patches and leave the remainder undisturbed until spring, when they may be transplanted with a trowel direct to flowering quarters. In some specially favoured southern gardens August sown seeds will germinate rapidly and be ready for transplanting by the beginning of October, making quite large plants, which in their sheltered situations will pass safely through winter and, of course, bloom very early next season.

Half hardy and tender annuals as well as the perfectly hardy kinds may, with advantage, be sown in autumn, in their case, necessarily, a greenhouse or pit which can be heated to exclude frost, being essential. Even with these, however, a close, stuffy atmosphere should be carefully avoided; ventilation should be free except in very bad weather, and artificial heat should be but sparingly allowed. October is quite a good month for sowing many of these seeds, and as growth may be steadily maintained throughout winter, the seedlings should be first pricked out, and then potted singly to produce strong, bushy plants for early flowering.

Cosmos is never so completely satisfactory as when treated in this manner. The customary drawback to the deserved popularity of this most charming flower is that its full display is made so late in the season that cold nights, drizzling rains and smutty fogs disfigure most of the flowers, but by sowing in October and potting twice, fine big plants may be secured which are ready to produce buds by the time they may be bedded out in spring. Each plant which has been well grown in a 48-sized pot, will fully cover a circle of 4ft. in diameter a few weeks after bedding, and the amount of elegant flowers for cutting, such plants will provide, in addition to a grand garden display, is truly remarkable.

Clarkias, godetias, nemesias, and a whole host of highly decorative annuals may be similarly treated with gratifying results, but always remember the shelves near the glass in the cooler, freely ventilated houses will afford more suitable winter accommodation for these seedlings than the closer atmosphere of a warm house.

Excellent plants of Kochia tricophylla may be produced from seeds sown at this season, and the useful climbing plants, such as Cobæa scandens, Eccremocarpus scaber and Mina lobata, usually sown in heat in February are much more satisfactory if sown in October and grown steadily along in a cool temperature.

The new Salvia splendens Harbinger has proved a suitable subject for autumn sowing. Watchful care is necessary to keep the seedlings just gently moving without any incitement to run away into soft, spindly growth, but although until January or February the seedlings are preferably kept small, the fact that they have made root is sufficient to ensure rapid development as soon as early spring days bring sunshine and a naturally buoyant atmosphere.

The remarkable thing about autumn sown annuals as compared with spring sown is that while they commence to bloom much earlier they attain such strength and development that the quantity of bloom is enormously increased, and so long as some pruning is indulged in, and removal of faded flowers and seed pods is regularly attended to, the autumn sown are quite capable of outlasting the spring sown, many of which begin to bloom before they have built up a strong enough framework to endure sustained effort. It is not too much to say that where the culture of annuals is confined entirely to spring sown seedlings the full capabilities of the best of them are seldom if ever realised.

L. I. ATRIS.

SERVICE FOR READERS

Though so many subjects are dealt with in each issue of THE GARDEN, it must constantly happen that readers seek information which is not immediately available. In such circumstances they should make use of our new Service Department. Through its medium each reader's own particular enquiry can be dealt with. No matter what the question is, whether advice is sought as to—

RESTOCKING A GARDEN, COLOUR SCHEMES FOR GARDENS, THE BEST PLANTS FOR CERTAIN SITUATIONS, WHERE TO OBTAIN NEW AND RARE PLANTS, INSECT PESTS, NAMING OF PLANTS, AND THE HUNDRED AND ONE OTHER DETAILS RELATING TO THE GARDEN—

there is always information available from a staff of expert contributors and consultants; *and there is no charge for this.* It is one of the additional means of Service which THE GARDEN is glad to render to its readers.

Also, there is the further convenience which the Service Department affords of supplying readers with data about anything that is advertised in the pages of the paper. Thus, on receipt of an enquiry, particulars will be sent of, say, half a dozen things about which the reader seeks information. The only stipulation is that a stamped addressed envelope shall be sent with the enquiry.

All communications should be addressed to the Service Department, THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C.2

CORRESPONDENCE

RED SAGE.

SIR,—Can any of your correspondents give any information about "Red Sage"? What the actual plant is, or where found? It was mentioned in the *Spectator* a little while ago as having great healing properties in cases of whooping cough, but I can ascertain nothing about its identity.—W. OSWALD WAIT.

FLOWERS FOR AN EGYPTIAN GARDEN.

SIR,—I send the following notes in the hope that they may help your correspondent, "A. B." who writes "An Enquiry" in your number of October 24th, about gardening in the desert suburbs of Cairo.

If expense is of no great object, it will pay her to cart in considerable quantities of Nile silt, which can readily be obtained from the Towns and Building Department of the Public Works, when canals are cleared in the winter. The cost of the mud is negligible, but carting such a distance from the naturally cultivated area must prove expensive. If plenty of this fertile mud is added to the sand, nearly all annuals, hardy and half-hardy, can be grown, also glorious roses and chrysanthemums, *not* herbaceous plants, as a general rule. If economy has to be studied it will be wise not to attempt to grow roses, which must have a fairly heavy soil.

Such plants as antirrhinums are always grown as annuals and these and the true annuals are planted in seed pans in the shade in June, July and August, to flower in February March and April. It is better to buy Christmas or early-flowering sweet peas, as these plants take so long to reach maturity that by the time the ordinary sorts come into flower the heat is too great for them and the plants collapse.

All the small annuals should be pricked out into pots and grown on in them to such a size that when transferred to the open ground they are not overpowered and smothered by the nutritious chocolate-coloured flood water. Egyptian gardeners love the pernickety work of pricking out, which allows them to squat for hours in some shady corner of the garden.

It is possible to have successful gardens right out in the desert, where the flowers grow in a medium of pure sand with old horse manure mixed in, provided that the water supply has its origin in Father Nile and does not come from the hard heart of a desert well. In such a garden the sturdiest of the annuals should be grown, such as sunflowers, coreopsis, zinnias, stocks and marigolds. Geraniums, cinerarias, freesias and chrysanthemums could be grown around the house in pots, with a little special soil.

There are many wonderful and accommodating sub-tropical flowering shrubs and creepers, many of which are almost too rampant and should be planted with care. The Agricultural Department in Cairo are ever ready to give advice to amateurs and to sell a percentage of their trees and shrubs, and there is a very excellent horticultural society, or was in 1922, whose members are always ready to lend a helping hand. I would suggest that your correspondent should start her garden with such plants as she can obtain locally and supplement this later with others from England.

Roses in Egypt always flourish best budded upon the native stock, a trailing, white-flowered rose called "sebawi," which can be grown from cuttings with great ease and certainty. Many native gardeners know how to bud, and friends will generally supply buds of a few good sorts, with which to make a start. The reason that I advocate this somewhat unusual method of laying the foundation of a rose garden is that the authorities open all cases of roses and other plants in the Customs House and fumigate them for fear of introducing pests, and after their attentions it sometimes happens that the poor roses give up the ghost. I should like to recommend as a guide to gardening in Egypt, "A Book on Gardening in the Subtropics," by Mary Stout and Madeline Agar, publishers, H. F. and G. Witherby, 326, High Holborn, W.C. This was brought out in 1921, but I know that it is still easily obtainable for I saw a copy of it in the book shelves at the Army and Navy Stores a month ago.—D. H. M.

ROMNEYA TRICHOCALYX.

SIR,—The enclosed photograph of Romneya trichocalyx may perhaps be of interest to some of the readers of THE GARDEN, to see how well it grows here in the Midlands. The original plant I grew from seed obtained from the Royal Horticultural Society about seven or eight years ago, and it has increased enormously by suckers which come up in every direction. Last winter I never even cut down the growths, and they remained untouched by frost.—LADY BEATRIX STANLEY, *Market Harborough.*

CALIFORNIAN POPPIES IN A MIDLAND GARDEN.

SOME LINUMS.

SIR,—In 1924 a plant of the dwarf Linum salsoloides nanum, "E. E. T.'s" desideratum, was obtained from Maurice Prichard's nurseries. It has flowered quite well the two summers that I have had it. It grows slowly and is only a small plant as yet. It is quite prostrate and creeping over the ground. Farrer's description and plate are quite good and fit my plant, excepting that my flowers are not "an unending succession"; perhaps they might be if the faded flowers were taken off. A little seed ripened in 1924, and much more this summer. It is in very poor, sandy, gritty soil, fully exposed to the south.

The plant to me is more like a prostrate dwarf L. suffruticosum than my L. salsoloides.

In June, 1924, L. suffruticosum was very plentiful in a locality at the east end of the Sierra Nevada at an altitude of about 5,000ft. and very lovely it was with its white (not snow white) flowers with black eyes (due to purple base to petals), profusely produced, large and wide open in the hot sunny days, closing up early in the afternoon. The plants were stiff, shrubby, twisted and quite dwarf, the flowers being on stems of about 6ins. Unfortunately, I was too early to obtain ripened seed.

My L. salsoloides was raised from seed some years ago, and is much larger and spreads out more than I care about. It has somewhat similar white flowers with smaller petals and on longer stems.

When visiting the late E. C. Buxton's delightful garden at Bettws-y-Coed in 1923, he kindly allowed me to take seed of a lovely white-flowered linum which I understood him to say had been brought by a friend from the south of Italy and which he had not been able to identify. It is an upright-growing plant with greenish (tending to glaucous) lanceolate acuminate alternate leaves and beautiful white terminal flowers; it is about 9ins. high at present, neat in habit, not a sprawler by any means, and—so far, at any rate—not a nuisance.—T. ASHTON LOFTHOUSE, *Middlesbrough.*

WINDOLITE.

SIR,—Referring to the note on Windolite, a substitute for glass, which appeared in THE GARDEN, October 17th, 1925, page 590, I would be obliged if you would let me know where this material can be obtained, and if you recommend its use.—E. L.

[This substance may be obtained from "Windolite," 179–185, Great Portland Street, London, W.1. We understand that during the past year this composition has been considerably improved, and is giving excellent results in the experiments which are at present being carried out by the Medical Research Council with a view to its more extensive use in all constructional works. As far as our reports go it is well worthy of a trial.—ED.]

ARBUTUS.

SIR,—I read with interest in your issue of October 31st, Mr. Bean's article on the "Arbutus," because I have been trying for some years to get A. photinæfolia, but without success. Perhaps Mr. Bean could tell me where I could get one, or if this catches the eye of a nurseryman, who can supply either A. photinæfolia or other hybrid varieties, which must be fairly hardy for this part of the world, would he kindly write to me? A. Unedo planted a few years ago is doing very well.—D. DOUGLAS OGILVIE, *Mylnefield, Invergowrie, Perthshire.*

ARBUTUS MENZIESII.

SIR,—In an article in THE GARDEN of October 31st, I noticed the paragraph referring to Arbutus Menziesii. I have one of these trees which I planted fifteen or sixteen years ago. It is now 18ft. to 20ft. high, with a girth of 3ft. It blooms every year, but late frosts have once or twice killed the flowers. So far it has not set any fruit. I would be pleased to hear if any of your readers have had similar experiences with this species.—JOHN RAWLINSON FORD, *North Lancs.*

ARBUTUS ANDRACHNE.

SIR,—Mr. Bean's article on the above (page 608) was most interesting to all lovers of trees, and should induce those who have space for same to plant arbutus. At Bicton, Devonshire, there are two good-sized trees of the above, one growing in low land among rhododendrons, kalmias, azaleas, etc., and though sheltered from high winds, it suffered somewhat when we had a storm, as did the one on much higher ground in the arboretum; good-sized branches were frequently torn off. The said trees flowered annually, but no fruits were ever noticed. It seems to me the wood is rather brittle and likely to suffer in exposed positions. It is certainly a most interesting tree when shedding its bark as well as when in flower. There is a good healthy specimen on the lawn at Cranmore Place, Chislehurst, and, although on high ground, does not show any signs of having suffered from abnormal weather at any time.—JAMES MAYNE.

FLEAS IN THE ROCK GARDEN.

SIR,—On returning from a holiday I was greatly interested to read an article by Mr. Elliott in THE GARDEN of September 26th on "Fleas in the Rock Garden." I, also, have had plants attacked, and as these were not members of the Cruciferæ, I think it desirable that the information should be made known. The first attack occurred in July on seedlings of Lonicera syringantha. Like Mr. Elliott, I noticed mysterious pits on the leaves, which after a time shrivelled up. On examining more closely I was surprised to observe a species of turnip flea jump away from them. It is not the species with the yellow spots which normally attacks turnips in this district. After killing the insects by hand, the plants grew away again in quite a healthy manner. Later on seedlings of Incarvillea brevipes in the same frame were attacked in like manner by the same species. I am indebted to Mr. Elliott for the excellent "tip" for catching them by means of fly papers. My attack being on seedlings in pots was defeated by hand picking. Out of doors this would, of course, be impossible.—E. B. ANDERSON, *Devon.*

BUTTERFLIES AND MICHAELMAS DAISIES.

SIR,—Like your correspondent "R. H.," I grow numbers of Michaelmas daisies in all prominent places because I love seeing the butterflies on them. This year we have remarked upon the absence of butterflies. In other years we have counted forty to fifty Peacocks at a time; this season we have not seen even one! Only two Red Admirals have we seen instead of large numbers. Other butterflies also were present in small numbers. Perhaps someone will give the reason.—M. K., *Nailsworth.*

VIBURNUM CARLESII.

SIR,—I notice in your correspondence, page 601 of THE GARDEN, Sir Herbert Maxwell's interesting remarks on my notes.

Here, at Winchester, there is seldom a leaf on Viburnum Carlesii by Christmas time and already this species is more than than half defoliated.

In connection with V. Carlesii Sir Herbert mentions the sometimes objectionable, though in some cases unavoidable, practice of grafting. This species, if taken at the right time, is comparatively easily rooted from cuttings, but is of slow growth afterwards. Seed, if it were procurable, would be the best and natural means of reproduction, but the plants would not flower in so young a state.

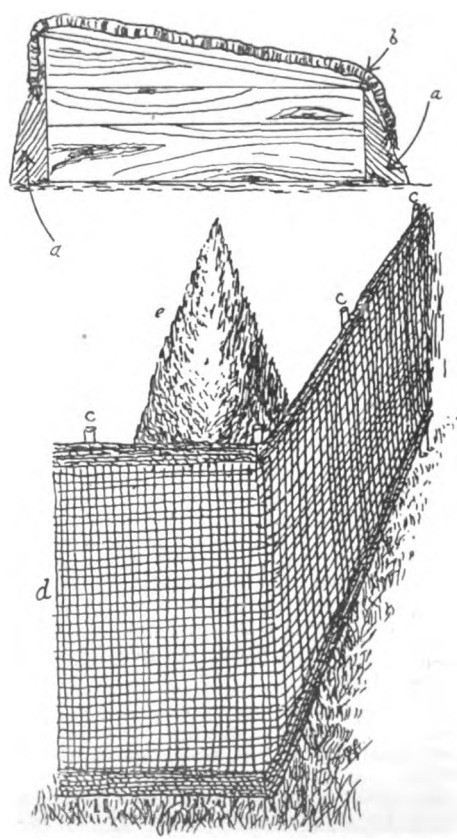
It is an interesting fact, Sir Herbert points out, that, whereas Spiræa arborea and its allies throw numerous suckers, S. Veitchii, up to the present, sends forth none.—H. G. HILLIER.

GARDEN TECHNIQUE

Notes on the Technical Side of the Garden and the Cultivation of Plants.

MATS AND MATTING FOR WINTER USE.

SOME of our most beautiful shrubs and plants require protection during the winter months, more or less according to the severity of the weather. Bedding-out and similar plants can rarely be kept in a healthy condition unless covered with straw litter or mats; cauliflowers being wintered in cold frames or temporary shelters in readiness for early planting out in spring, are generally safe if mats are placed over them on very frosty nights, and it is absolutely necessary to use mats or litter where early vegetables are being forced in frames or salad plants are blanched. Coir fibre matting, properly placed, would save thousands of young trees and shrubs and hundreds of thousands of border plants when newly planted in exposed positions, especially in exposed places and on the sea coast. I remember, many years ago, a laurustinus hedge was planted near a low wall facing the sea, a quarter of a mile from the tidal waters. The plants did well as long as they had a shelter afforded by the wall, but above its level the young wood was regularly killed several inches back every year. Then a fine-meshed wire netting was fixed on the wall and the laurustinus grew splendidly. On the south coast, the south-west winds kill back many valuable shrubs and plants that are left unprotected in a young state, and from personal experience I know how necessary it is to use a wind-break formed of mats, hurdles or coir fibre wind-screening. Not only is it advisable to keep all covering mats dry to ensure them lasting a long time, but on account of their greater resistance to frost when in a dry condition. Many years ago, when bedding



out plants—except the more tender ones—were wintered in frames, straw litter and Archangel mats were the two principal kinds of materials used to exclude frosts. Frost penetrates damp, cold straw sooner than lightly placed dry straw and this applies to mats and matting, too. In a northern county a nurseryman saved his plants in frames by staying up all night, during a specially severe frost, and lightly turning and tossing the surface portion of the litter. Others in the same district lost many plants. If a sturdy hedge is near, the mats, when not on the frames, may be spread out there to dry. Failing a hedge, erect a few posts to support strong wire on which suspend the mats. Frequently frost penetrates to plants when mats are used, and even a thick layer of straw, when the covering material is not put on correctly. The edges and sides of the frames should be well covered as well as the glass lights. I have found the most effective covering in a severe frost to be, first, a layer of mats, and, second, a layer of dry litter on them—the sides of the frames being well covered, too. The Darjeeling mats are splendid, keep out frost, may be rolled up and last quite a considerable time. Old sacks, split open and sewn together, single or several in thickness, form good mats. It is important that all covering material be left on frames or plants, after a frost, till the thaw is complete. Good covering mats may be made of Frigi-Domo and Hessian. When ordering mats, have them a trifle too large, rather than too small.

The end of an ordinary frame is shown in the accompanying sketch. At *a*, *a*, some dry litter should be heaped against the sides and ends and the mat *b* placed over frame lights and litter if the mats are not large enough

Digitized by Google

to reach the ground. To protect choice trees, plants or shrubs against south-west and north east winds, fix stakes *c*, *c*, *c*, to support the mats or matting. Full protection would mean having the matting as high as the tree *e*.—G. G.

SWEET PEAS.

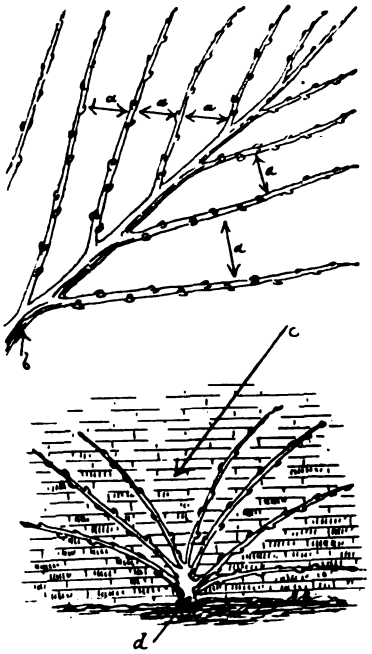
PROBABLY no flowers, certainly no annual flowers, will repay one so bounteously for correct and careful preparation of their flowering site as the sweet pea. Often I have stated the fact that they will grow and succeed in almost any kind of soil or situation, but the better that soil is prepared the better will be the results.

All soils require "knowing" to a certain extent, and although they may vary in their nature to a very great degree, the broad outline of correct treatment holds good in almost all instances. If I were asked to indicate in three words the chief points to bear in mind in soil preparation for sweet peas, those words would be "Early," "Deeply" and "Liberally."

By an "early preparation" of the soil I imply digging or trenching it in the autumn, the earlier the better. This gives the ground a chance to settle—for sweet peas like a firm rooting medium—and take full advantage of the disintegrating action of winter frosts and rains. Again, by early digging the manures which have been incorporated have ample time to "break up" into a form which can be readily assimilated by the roots at the time when nutriment is most needed by the plants. With soils of a clayey nature, or on the heavy side, autumn digging is not only advisable, but a necessity, for if this should be postponed until the early spring it will most likely be in a lumpy or sticky condition when the plants are transplanted, and develop a hard, unworkable and unaerated surface layer later. I do not know exactly how far down sweet pea roots will travel, but if soil conditions permit I should estimate quite two-thirds as far underground as their foliage reaches above the surface. Do not misunderstand me, for I do not mean that it is therefore necessary, or even beneficial, to move the soil to a depth of 6ft. or 8ft. From 2ft. to 3ft. deep is ample whatever objects one may have in view, even for exhibition purposes. Of course, excellent blooms may be obtained by simply digging one spit deep and turning in animal manure as for an ordinary vegetable crop, but where circumstances will allow I advise 2ft. as the minimum depth. The deeper and more extensive their root system—within reasonable limits—the healthier will be the plants, and, further, they will be much more likely to withstand adverse weather conditions, drought, excessive rain and sudden weather changes. C. H. A. S.

TRAINING AND TYING PEACH TREES.

A PEACH tree, if in a healthy state, will make many shoots in the course of a season—from March to the end of September. The owner must very carefully watch his trees and disbud during the summertime very freely, so as to avoid any severe winter pruning. But only expert cultivators do this; the majority leave in these freely-produced branches and then overcrowding is certain to occur and this means the ruin of the peach or nectarine as regards fruit bearing. Where it is found, now, necessary to cut out any shoots, remove those badly placed; do not cut out very strong unripe shoots, but wait until the young wood buds grow next spring, then rub all these off and cut away the branch itself when the tree is in full growth, smearing the wound with Gishurst compound to prevent the formation of gum. The young shoots *a*, *a*, *a*, *a*, *a*, should be trained at least 4ins. apart; 6ins. would be better. The bottom part of a tree should be filled first and to do this it may be necessary to bring down main branches *b*. The centre of a tree should be the least crowded part



of it and in the case of a newly-planted one the letter *c* shows how this is done. In doing the work of planting, none of the main stem *d* should be buried. This is a very important point.

PLANTING GREENHOUSE CLIMBERS.

CLIMBERS for greenhouse and conservatories should be selected suitable for the size of the structures in which they are to grow. It would not be wise to plant, for instance, a Cobæa scandens in a tiny greenhouse, because this and similar plants require a lot of space in which to grow to the best advantage. Lofty, spacious houses are splendid for accommodating such noble-looking plants as bougainvillea, habrothamnus, tacsonia and Solanum jasminoides floribundum. Pillars, back walls and wires immediately over the paths are all suitable positions for furnishing with climbing plants; one of the best for training to wires over the path is Clematis indivisa lobata, its beautiful deep green glossy leaves are there practically all the year round on a healthy plant, as it is evergreen. Hoya carnosa is a little gem and may be grown in a small space; Lapageria alba and rosea and rosea superba, look well on a trellis or a pillar, also hanging from the wires under the roof. Swainsonia galegifolia and the white variety alba do nicely on back walls, when there is light, but little sunshine; Bougainvillea glabra is best trained up supports under the roof glass and treated much the same as a grape vine. Jasminums form charming pillar and trellis plants. Plumbago capensis adds a lovely blue colour to the collection. All climbing plants may be grown in large pots and tubs, as well as in prepared borders. Good fibrous loam and sweet leaf soil with the addition of a little mortar rubble will form a compost for the majority while peat may be used for a few kinds.—HANTS.

VIOLETS ON A NORTH BANK.

IN many gardens there is a bank with a north aspect, at the back of which there is a hedge. Such a position does not get a great deal of sunshine, and there are few flowering plants which would give good results where there is so much shade. It is worth noting that a situation of this description is almost ideal for violet culture. One might, indeed, give the whole of the bank over to the little plants and, in any likely season, rarely be without the fragrant flowers. To give the best results violets must have a certain amount of shelter, which should preferably be a hedge, or, at any rate, a more or less open fence. A wall is the least satisfactory of all behind the violet bank. Those who grow violets on a bank facing north or north-east will be amazed at the way in which the plants fourish. This is in striking contrast to their poor development when the aspect of the bank is south. Before putting in the plants prepare the bank carefully. If the soil happens to be light and with much gravel, some stiff material and plenty of manure should be worked in. On a bank formed of stiff clay, dig in sharp gritty matter freely in addition to some well rotted manure.—LEONARD BASTIN.

THE TREATMENT OF LOBELIA CARDINALIS DURING THE WINTER.

A GARDENER of many years' experience with herbaceous plants once asked me how we managed to keep Lobelia cardinalis through the winter, and remarked at the same time that he lost all his plants in winter. It was that question, combined with what I might term the "no-difficulty" method which we follow each year with our lobelia plants, that has prompted me to give my experience. This handsome North American plant was introduced in 1626, and is, therefore, an old inhabitant of our gardens. It is also known as the cardinal flower; but "in our climate it is not perfectly hardy," and therefore it requires protection in winter.

Our method has always been to lift the plants with plenty of the border soil about their roots, and accommodate them in cutting boxes before severe weather sets in. The roots are set close together in the boxes, and any spaces left are filled with fine sandy soil or flaky leaf-mould. Then the boxes are placed underneath the staging—but where they will receive light—in one of the vineries. No water is given to the roots. If this practice is followed, no one should have any difficulty in keeping the roots of Lobelia cardinalis in a healthy state throughout the winter. In fact, I have seen plants come through the winter when left out in the open border. In spring, when the plants start into growth, they should be divided and the strongest stems selected and set out in good rich soil in other boxes. These plants should be grown on in a moderate temperature until established; then the boxes should be placed in frames and the plants gradually hardened off, until such time as they can be left in the open with safety, when they may be set in the flower beds or borders.—DAVID ARMSTRONG.

THE VALUE OF LEAF-SOIL.

THE leaves are now falling fast, and in gardens where trees abound the broom should be in constant use. The results of labour thus expended are always satisfactory, firstly by the greatly improved appearance of the garden itself, and secondly by the value of the leaves so collected. Leaf-mould is much and deservedly valued for mixing with the soil for potting different plants, and cultivators ought to see that they obtain a supply of it. It is the accumulation year after year of the fallen leaves of the woods that produce the rich dark soil that supports the fine forest trees and the ferns and flowers that carpet the ground above their roots, rendering the woodlands so delightful during spring and early summer. This decayed matter is equally valuable

Digitized by Google

in the cultivation of nearly all kinds of garden flowers, as well as plants in pots, and may be used in the garden as a mulch during the summer and afterwards dug in. It may also be used freely when digging or trenching is done. If it be sifted it will do well for mixing with soil for seed sowing, pricking off seedlings, etc.

The best leaves for forming mould are oak leaves, while beech leaves are also valuable, and where these can be procured, a good plan is to have hurdles erected behind a hedge or in a corner angle of the garden, and as fast as the leaves are collected they can be thrown into this, wetted, and a few shovelfuls of earth thrown over them to keep them together. Another way is to place the leaves in pits covered with a little earth, and so get a genial warmth for cuttings in spring and summer; while, when the next autumn comes, this will provide a good supply of the finest mould obtainable. The leaves should be turned every two or three months and well shaken up during the process. This will assist decay, and also help to prevent the growth of injurious fungi among the leaves.

Hot-beds are often useful for such things as asparagus, rhubarb, seakale, lettuces, radishes and other vegetables which may be required, and the bulk of the material may be leaves; but there should be enough stable manure to hold the leaves together and throw a little energy into the fermentation. Lily of the valley, pot-grown bulbs and other plants may be brought on in a leaf-bed; and there is no better way of starting early strawberries till the flower spikes are showing. Pot roses will do well in a pit filled—or partly filled—with leaves. The blooms and foliage come clean and strong under such conditions. —R. D.

PLANTING ROSES.

ROSES may be planted at any time, during open weather, from November to early in April, according to soil conditions. The ideal time, of course, is in November and the first half of December; the latest date being suitable only in cases where it has not been convenient to plant earlier. Scores of thousands of roses are planted every year and a big percentage fail to grow satisfactorily, many dying. The plants are often very badly treated; they are lifted in a rough manner, unduly exposed to the air and, frequently, frost. Plants so treated cannot be expected to yield fine blooms the following year. It is only inexperienced and careless persons who treat the plants in this way. The cultivator, directly he receives the plants from the nursery, should immerse the roots, packing material as well, in a cistern or tub of water, allowing all so to remain for at least one night. Then carefully unpack and place the plants in a shallow trench on a north border, covering the roots with soil, after cutting off the ends of any that are bruised. If the weather is frosty when the plants arrive, place the bundles, unpacked, in a cool, dry shed and safe from frost. Leave them so till the thaw is complete. Immerse the roots in water before planting. Roses thrive in a stiff soil, but, nevertheless, I like to have a nice heap of almost dust-dry light soil in a shed available at the time of planting; a small spadeful sprinkled on the roots before the latter are covered with the garden soil does good eventually, as the soil is rarely quite dry at this season.—HANTS.

ST. BRIGID ANEMONES.

THESE lovely flowers may be gathered from October to early summer, if care be taken to plant strong corms in various situations—warm ones and in cool, north borders. Seeds sown in spring will yield plants that will bloom the following autumn and throughout the winter months. Seeds may also be sown in the autumn, indeed, in almost every month of the year. I know that some lovers of these flowers are under the impression that the plants will not thrive in a clayey soil. A few years ago I had a few young seedlings given to me by a friend. Being much pressed for time when I came home, and not wishing the plants to shrivel, I hastily "heeled" them in in a clayey, pasty border for the time being. But they were left there and have so remained for the past four years. Every year these plants have made grand growth and borne fine flowers. So cultivators need not hesitate to plant in such soil if it is in a suitable condition at the time. One defect of these flowers in some instances, is the shortness of the flower stem. I find it is longer on plants growing in a heavy, than on plants in a light soil. But I recommend cold frame culture where long stems and very clean flowers are required. It may be possible, in many gardens, to place a frame on plants where they are growing in the open border; if so, the result would be very interesting. It is important that all beds of these anemones be thoroughly cleaned before frosty weather comes.—CHRISTCHURCH.

PLANTING AND STAKING TREES AND SHRUBS.

THERE are odd specimens, clumps and new gardens to be planted from autumn to May. Even in the case of the single specimen it is advisable to dig the soil deeply and to loosen and break up the sub-soil. In the case of clumps and large borders general trenching of the soil is advisable. One rarely travels a few miles through town or country without seeing both trees and shrubs planted in wrong positions. The planter should understand what each tree or shrub is capable of doing in the matter of growth and select a position accordingly, so that, when the tree is practically fully developed it will be quite clear of drive, path or other specimen tree and show to the best advantage. It may be necessary to fill up vacant space with other kinds of trees or shrubs, but care should be taken that these do not interfere with the growth of the permanent specimen. This rule applies in the case of the big tree and the smaller specimen shrub, equally. It is, of course, another matter, but I may refer to it here, namely, the cutting out in future years: it should always be done in good time, before the permanent tree is damaged by overcrowding. Every specimen over 2ft. in height, in exposed positions, should be staked. Strong winds loosen the roots in the soil and delay the recovery of the shifted plant. If held firmly in position the tree or shrub soon forms new roots and new branches. Single stakes are sufficient for dwarf specimens, but tripod staking is best in the case of tall specimens.

WALLFLOWERS.

HUNDREDS of thousands of wallflower plants are raised every year and a big percentage of them are spoiled during their early stages of growth and another big percentage of them are wasted—thrown on the rubbish heap. Of course, it is too late, now, to sow seeds; I am dealing with stocks of plants now available in almost every garden. The pampered plants, raised in boxes, require very careful treatment or they will not be very satisfactory; those overcrowded in their seed beds also require care or good results cannot follow. Those from the open border, transplanted or not overcrowded, are the ones that afford us most satisfaction. The wallflower is quite hardy, but if the plants are disturbed and replanted during frosty weather, they suffer a very severe check, so also do plants grown in a very rich medium, when, in an open early winter-time, they grow rather luxuriantly and suffer from frosts. Moreover, these big sappy-stemmed plants do not yield the finest spikes of flowers, though individual ones may be large. An ideal soil is one of medium richness and containing some lime or old mortar rubble. The soil should be firmed while in a fairly dry condition. Lift the plants with the aid of a hand fork or trowel; if very large, use a garden fork. Transplant firmly and allow a space of one square foot per plant—nine to a square yard—then every specimen will be bushy, sturdy, even in height, and bear the finest flowers.—G. GARNER.

CARDOONS.

MCINTOSH remarks, in his book, the "Practical Gardener," that "There are four sorts known to cultivators in this country, although there is seldom more than one sort grown and that only in gardens of the first class." It seems that these remarks are quite applicable at the present time, although written eighty years ago, as cardoons are never seen in gardens. Their cultivation need not deter any enthusiastic amateur from growing splendid plants if these few details are followed. We have sown seed in the middle of April and in the middle of May, and from each sowing excellent results have been obtained. Our method is to sow the seeds—which are easily handled—in a box containing ordinary fine soil, then set the box in heat. In less than a month from date of sowing, the seedlings are placed singly in 4in. pots and kept in heat until the roots are well established in the fresh soil. Then the plants are moved to a frame and gradually hardened off. In June a trench is dug—in a sunny position—15ins. broad and 15ins. deep; in the bottom, and incorporated with the soil there, is spread a good dressing of decayed farmyard manure. Then a good layer of old potting soil—such as that left from the old pot chrysanthemums—is spread over, and the plants set out 1ft. apart in one long line in the centre of the trench. It may be interesting to state here that the foliage on well grown plants of the large Spanish cardoons resembles that of the globe artichokes. About the middle of September the stems should be tied with matting and the earth banked up on each side of the line of plants similar to the earthing up of celery. In four or five weeks time from date of earthing up the stems should be ready for use in the kitchen.—DAVID ARMSTRONG.

SALVIA ULIGINOSA.

A FINE but none too common plant now flowering profusely in the herbaceous border is the gentian blue sage, Salvia uliginosa. It is a beautiful hardy species from Brazil, and when shown before the Royal Horticultural Society on September 9th, 1913, it received an award of merit. It is not really fastidious in regard to soil or position, except dense shade, and thrives best where the border is not too dry during the summer months. Attaining a height of 4ft. or 5ft., the plant has a graceful, freely branching habit, and the flowers, although not nearly so large as S. patens, are numerous, a large number being open at the same time. It commences to bloom towards the end of July, and continues in full beauty until cut down by frosts. When the borders are dug over a little manure should be placed near the roots, and the clumps divided if necessary. The outside pieces are best for planting, and for preference it should be placed near the white Anemone japonica, where it will prove extremely effective. Propagation is effected by division and cuttings, the latter being taken in September or October, and they readily form roots in a cold frame if set in boxes containing sandy soil.—T. W. B.

ORCHIDS FOR THE AMATEUR

PROBABLY few gardeners realise that the Orchidaceæ is now the largest of all plant families, with over 16,000 recorded species, exceeding the swarms of Compositæ that are found scattered throughout the world and which for many years held the first place in numbers.

A large volume could be written on the history of orchids, for their exotic appearance and the tropical jungles in which they grow cast a glamour over this wonderful plant family. Expedition after expedition has been sent out through every corner of the tropical world and through them have been imported many thousands of plants. One expedition to New Guinea alone, between 1907 and 1909, sent home as many as 1,102 new species. The hybridist has also cast his spell over them. It is recorded in the "Hortus Veitchii" how Mr. John Harris, a surgeon of Exeter, first suggested to John Dominy, one of Messrs. Veitch's gardeners, the possibility of getting hybrid orchids, and explained to him the structure of the orchid flower and the process of pollination. The result of the first experiment flowered in 1856, Calanthe × Dominii. The popularity of orchids increased rapidly, not only among gardeners but also among collectors of plants, and the prices rose with astonishing rapidity. As long ago as 1879 nearly £100 was given for a single plant of Vanda cœrulea, which can now be bought for one guinea or less. Many will remember the small fortunes that were often given for a striking new hybrid odontoglossum in the early years of this century. Probably the very intensity of this craze for the newest and the rarest helped to bring about the decrease in the value of orchids as much as war conditions, for the ordinary gardener fought shy of growing plants which brought in such fantastic prices. Now that the war is over and gardening conditions are more stable, orchids are again becoming fashionable.

It is a pity that their popularity has suffered a temporary set-back, for some of the genera respond excellently well to ordinary greenhouse treatment. They possess many advantages: the time the flower lasts, ease of cultivation, length of life of the plant. Many cypripediums, vandas, dendrobiums and cymbidiums fall into this class, as well as many other varieties and species, while some would prove perfectly amenable even to cold-house treatment. As an example of the latter Farrer and I found Cœlogyne cristata in Upper Burma smothering the branches of trees in waterfalls of the snowiest white, and this at an altitude of 10,800ft., where for four months of the year everything was covered with a mantle of snow. Plants from that part of the world have a peculiar temperament, and I cannot say for certain that they would grow outside in our climate, although I should imagine they would; but here is surely a plant that is ideal for a cool greenhouse.

All the genera I have mentioned have attractive flowers. Everyone knows the smiling faces of the slipper orchids and those who see the marvellous exhibits of the trade and of the few amateurs who still show must realise the brilliance of colour and marking of the newer hybrids. Vanda cœrulea is one of the most lovely of all orchids to my mind, with its delicate arched spike of pale lilac-blue flowers. Dendrobiums are old favourites. They never reached the amazing prices of odontoglossums and have always been an orchid for the average gardener, partly because of their floriferousness and for the fact that they flower with the same vigour year after year. Cymbidiums are newer favourites, but they are so absolutely suited to ordinary greenhouse treatment that even people who have no desire to own a collection of orchids have realised their decorative qualities. And so the tale might run on. Many genera have some quality or other that appeals to the ordinary gardener.

As we feel that the time has come to give the orchid a help to regain, not the crazy popularity of the early twentieth century but a more lasting home in the greenhouses of the great mass of gardeners, THE GARDEN has arranged with Mr. Gurney Wilson, the secretary of the R.H.S. Orchid Committee, who knows as much about these fascinating plants as anyone, to write a series of articles showing how orchids can be grown in the ordinary greenhouse. The first portion appears in this issue, dealing with cypripediums, and it will be seen that not only is this genus described and cultural details given, but a dozen varieties are also listed which are eminently satisfactory either as a nucleus for perhaps a larger collection, or as a group by themselves. I feel confident, however, that those who start orchids, however hesitatingly, will never give them up, for the orchid has not only a background and a glamour around it, but is lovely enough to ensure its own popularity once it is given a fair trial.

E. H. M. C.

AMONG THE ARTICLES IN OUR NEXT ISSUE WILL BE:

THE BIRCHES, by E. H. Wilson.

DENDROBIUMS OF THE NOBILE SECTION, by Gurney Wilson.

SUMMER AND WINTER MULCHING, by J. Coutts.

GREENHOUSE CYPRIPEDIUMS

BY GURNEY WILSON.

LOOKING back over the records of many years, one is convinced more than ever of the great popularity which cypripediums have enjoyed. Notwithstanding the present-day attractions of other sections of the orchid family, the genus cypripedium is one which more than holds its own in the competition for supremacy. If we seek the reason, it will be found in its suitability to the climatic conditions existing in the majority of amateurs' greenhouses. Its terrestrial habit of growth allows it to be grown in company with most of the occupants usually seen in an ordinary collection of greenhouse plants, and even if nothing better than the customary potting soil is used as a rooting medium, the results are quite satisfactory. These simple requirements explain why cypripipediums came into popularity at such an early date in the history of orchid cultivation. In fact, most of the amateur and trade growers soon discovered that, with little more than the usual attention as regards potting and watering, these plants actually acquired a more vigorous condition than they possessed in their native homes. With such a responsive nature to the simple requirements of life, what other plants are better adapted to the needs of an amateur.

More than a century has elapsed since Cypripedium insigne was first sent to England from north-east India. C. insigne var. Harefield Hall, is a real giant of its kind, while C. insigne Sanderæ, with its flowers of clear primrose yellow colour, is too well known to need further description. Both varieties have been propagated to an enormous extent.

The year 1869 marked the flowering of the first hybrid cypripedium. It had been produced by crossing C. villosum with the pollen of C. barbatum, and was named C. Harrisianum in honour of Dr. Harris, of Exeter, who first gave to Dominy the idea of hybridising orchids. Of the many thousands of different cypripedium hybrids that have since been raised it is possible to select a very wide range, varying from the pure white flowers of C. niveum, through all tints of yellow, to the darkest shades of crimson-purple.

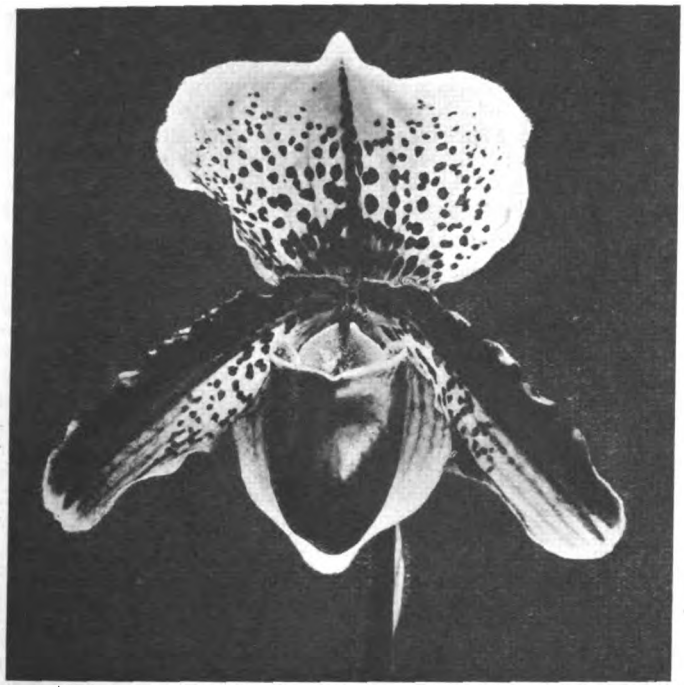
The generic name, cypripedium, is, in reference to the slipper-like form of the labellum, hence the common name, lady's slipper orchid, so familiar to everyone. But although the slipper-like organ of the flower is such a characteristic feature of the genus, it has never received anything like the attention that has been bestowed upon the dorsal sepal, which, in consequence of its more showy nature, is recognised as the principal segment. Even the typical C. insigne has its chief attractions in the dorsal sepal, while in C. Spicerianum there exists a species whose dorsal sepal of porcelain white nature has rendered it of immense importance in the production of beautiful hybrids. No better example exists than C. Leeanum (insigne × Spicerianum), for it combines in a most pleasing manner the chief characters of both parental species. Its large dorsal sepal is white, prettily marked with small, purplish dots arranged in vertical lines. Mention may here be made of C. Leeanum giganteum, for it constitutes one of the best examples of a hybrid orchid producing flowers larger than those of either parent, while the plant itself possesses a more robust constitution. When one considers the flatly displayed nature of this dorsal sepal, with its brightly coloured markings, it is easy to understand why not a few amateurs like to call their favourite cypripediums the Banner Flowers.

A GROUP OF CYPRIPEDIUM FAIRRIEANUM.

ONE OF THE MOST BEAUTIFUL OF THE GENUS, C. MAUDIÆ.

The first flowering in England of C. Fairrieanum created quite a sensation, for its beautiful formation and delicate tracery of colour surpassed all existing forms. Now we have an extensive series of Fairrieanum hybrids. No one who has cultivated C. Niobe (Fairrieanum × Spicerianum), will readily forget the fascinating characters of its artistic flowers, yet this is but one of a large number of beautiful lady's slipper orchids that can be successfully cultivated by any amateur, and which require no more care than that given to a maidenhair fern, or other shade-loving plant.

During the period when cypripediums were being imported in tens of thousands, considerable interest and speculation were attached to the first flowering of the plants under artificial cultivation. Just as C. insigne yielded a variety of primrose yellow colour, due to the elimination of the purple, so in turn most of the other species have produced the so-called "albino"



CYPRIPEDIUM ELATIOR VAR. SHRUBBERY.

varieties. This term is somewhat inappropriate, for the flowers are not pure white, but consist of examples in which only the purple pigment has vanished, the yellow or green colour remaining, as the case may be. Two other cypripediums of importance exist in the "albino" varieties of C. callosum and C. Lawrenceanum; and as both produce elegant flowers of a light greenish colour, the hybridists very soon crossed the one with the other and produced the popular C. Maudiæ, one of the most beautiful cypripediums that has ever been raised.

While C. insigne and several other species will withstand a temperature almost as low as freezing point, favourable results are obtained with a minimum of 45°. There are other species inhabitating warmer climates, and these must on that account receive a higher temperature. Amateurs who do not maintain warm-house conditions should avoid the tropical cypripediums, which is a matter that need cause no regret, for the number of suitable species and hybrids is far in excess of all ordinary requirements. Although ordinary soils of a fibrous nature will produce fairly good results, there is nothing like a mixture of loam, sphagnum moss, and peat for obtaining excellent plants and flowers.

The majority of cypripediums do not require re-potting more than once a year. Generally speaking, this is best accomplished when the new growths are two or three inches high, but should any plant get into a water-logged condition, no delay must be allowed in correcting the trouble. All decayed compost must be carefully removed, as well as any dead roots, and the plant placed in a pot of suitable size, the compost being worked in among the roots with a potting-stick, and finally pressed down firmly. Large specimens are not so fashionable as they were, and small plants prove of greater utility. Propagation is effected by severing the growths with a knife.

While many orchids are naturally subjected to prolonged periods of drought, and on that account are provided with pseudo-bulbs to store up the necessary moisture, cypripediums differ considerably, for being of terrestrial habit and accustomed to moist conditions throughout the entire year, it is absolutely essential that a moist atmosphere be at all times maintained. During fine weather the foliage may be occasionally sprayed, and so long as the temperature remains suitably high, the atmosphere should be kept moist by frequent damping down of the floor. During very cold weather, care must be taken that water does not lodge in the growths, for damage may thereby be caused if the temperature of the house becomes unreasonably low.

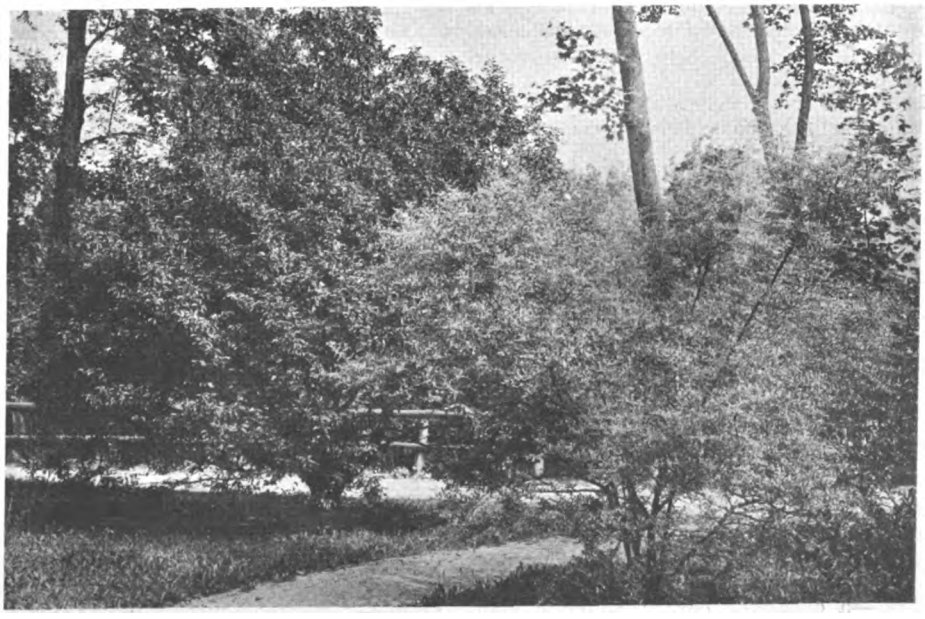
Another important point is that the plants must be protected from bright sunshine. They are, in fact, shade-loving plants. More cypripediums have been damaged through insufficient shading than by any other cause.

In C. Elatior there exists an elegant hybrid which is composed of the species and hybrids already referred to in this article. It contains insigne, Fairrieanum, Leeanum and Harrisianum, and is thus particularly suitable for an amateur's collection. The accompanying illustration depicts the Shrubbery variety of C. Elatior, to which a first-class certificate was awarded by the Royal Horticultural Society a few years ago.

In addition to the above mentioned kinds, a really useful dozen cypripedium hybrids can be recommended in aureum, gigas, Hera, Lathamianum, Lord Wolmer, Minos, nitens, Priam, Rossettii, Thalia, Troilus and W. R. Lee. All of these are easily procurable from the trade growers, and at very moderate prices. During recent years some new hybrids, with unusually large flowers have been produced, but at present they command too high a price to be entertained by the general amateur.

THE BEAUTY OF PRIVETS AS SPECIMEN PLANTS

SPECIES like the common or the California privet are two of the most useful plants of our gardens. Especially the last-named Japanese species, Ligustrum ovalifolium, which in America is called the Californian privet. It is a well known hedge plant with glabrous half-evergreen leaves of a glossy surface. Mr. Bean says that it is not worthy of being put to better use, being of stiff, ungainly habit, its flowers dull and, to most people, evil-smelling. This may all be true, but if we meet with a large well grown plant like that in the illustration overleaf, which stood in a Dutch garden, we are rather surprised by its natural beauty. The specimen measured about 12 feet in height. It was an exceptionally fine one, and I have never seen a plant of L. ovalifolium like it. The other Japanese privets with real evergreen leaves, like L. japonicum and L. ucidum, are very handsome larger shrubs, or even small trees, with larger, firmer leaves, and they belong to a different section on account of their flowers. To the same group as L. ovalifolium, with a



LIGUSTRUM QUIHOUI WITH PRUNUS LUSITANICA.

Digitized by Google

long corolla tube, belong the Japanese L. acuminatum, L. amurense and L. Ibota, the latter now called L. obtusifolium. Of these, L. amurense is rather similar in habit to L. ovalifolium, and often semi-evergreen too. As its name indicates, it is more widely spread than the Californian privet, occurring in the region of the Amur and also in northern China. It seems to be rather rare in our gardens, and I do not remember ever having seen a good plant of it. It has, of course, nothing to do with syringa or Ligustrina amurensis, and it is said to be found in some collections under the name L. Ibota var. amurense. The true L. Ibota or obtusifolium is, however, a well known plant of a different habit, forming dense broad bushes with gracefully spreading and curving branches. Its small, short, nodding inflorescences appear in great profusion, especially on the Continent, because the species of ligustrum with deciduous leaves prefers a Continental climate. L. Regelianum, that usually is regarded as a mere variety of L. obtusifolium, forms even dwarfer and denser bushes with almost horizontally spreading branches, and is, in my opinion, less ornamental than the type.

A SPECIMEN PLANT OF THE COMMON PRIVET.

To the same group as the species mentioned above (section Ibota of Koehne) three more species are to be reckoned. Two are from central China: L. Henryi and L. Delavayanum or L. Prattii, and the third one comes from the eastern Himalayas: L. Massalongianum. All are evergreen shrubs, and the Chinese species become bushes up to 13 feet tall but hitherto I have not seen large cultivated plants. I know, however, L. ionandrum from Yunnan, which, according to Rehder, is possibly only a form of L. Delavayanum with stunted flowering branchlets and short dense panicles. L. ionandrum forms dense roundish shrubs closely resembling Syringa sempervirens, which is now Parasyringa sempervirens. Of L. Delavayanum there seem to be several forms, some of them rather like L. ovalifolium in habit. It was introduced long ago by Abbé Delavay, and I first saw it in 1906 in the collection of the late M. L. de Vilmorin at Les Barres. Its branchlets are densely covered with a short pubescence. This is the same in L. Henryi, which seems to be altogether a much more showy species. Both have small oval or almost roundish leaves. In this respect they differ widely from L. Massalongianum with its linear-lanceolate leaves. I know it only from some Mediterranean gardens, and it is, apparently not hardy, except, perhaps, in the warmest parts of the British Isles. It looks very pretty when in flower. There is a species in western China related to it and named L. gracile by Rehder. So far as I know, it has not yet been introduced.

Of the other section of the genus, representing the typical ligustrums, I have already mentioned the evergreen L. japonicum and L. lucidum, which are among the best broad-leaved evergreens in the gardens of southern Europe. In many gardens of Spain I met with the variegated-leaved variety of L. lucidum, var. tricolor, forming large dense almost tree-like bushes of which the leaves show a distinct yellowish variegation and an irregular border of white; besides this they are pinkish when young. The three or even four colours make a rather curious but not unpleasant impression. There are apparently some hybrid forms in existence between L. japonicum and L. lucidum. I saw plants under names like L. Kellermanni, L. magnoliæfolium and L. Sieboldii that may partly represent such hybrids.

I have never been sure about such species as L. nepalense and L. Walkeri. The latter comes from Ceylon and the Neilgherries, and I do not think that any form I have met with under this name has anything to do with the true species. There are, however, quite a few forms in our gardens that are almost evergreen, and not identical with species of the Ibota group. I suppose they are mostly of a hybrid origin, and it may be that the true L. nepalense or even L. Walkeri is mixed up in the parentage. L. vulgare, which has half-evergreen forms (var. italicum or sempervirens), or L. sinense, which sometimes in mild winters is nearly evergreen, may easily hybridise with nepalense or Walkeri. L. sinense is one of the best species for ornamental purposes; it is, however, an exceedingly variable plant, and apparently widely spread from central China to Korea. It is often mistaken for L. amurense.

Of almost equal horticultural value with L. sinense is L. Quihoui (L. brachystachium), from central and northern China. It is one of the most graceful privets, and of special interest on account of its late flowering time. Its name sounds rather strange, and was given in honour of Mr. Quihou, who was the superintendent of the Jardin d'Acclimatation at Paris in the sixties of last century, when this species was introduced to France from northern China.

There is still one Chinese privet that ought to be mentioned, the evergreen L. strongylophyllum, with small, almost orbicular leaves. It is less hardy than L. Delavayanum.

CAMILLO SCHNEIDER.

A ROCK GARDEN OF THE NORTH

THERE is a disposition to think of the rock garden as a thing apart—a place that begins just here and ends just there, without relation to the garden proper. Either it is a poor relation, as it were, of the herbaceous spaces, to be tucked out of sight; or it is kept sacrosanct, as if its owner told you in so many words that here is something almost too rare for human nature's daily food—a cloistered corner, to be hidden from the rough ways of men.

The particular garden I have in mind was not built in sections of this kind. Its whole being has developed under wider and more natural auspices. But, then, its situation asked no less.

Picture to yourself a trout stream, running wide and shallow—except in flood times—from the near moors. It goes under thick-boled sycamores and slenderer beeches. Across the hipping stones—stepping stones, in newer English—a cart track goes to the meadows. They name it Lovers' Lane. In July the hay wagons come lilting home, spreading their wares on the thorn hedges as they pass. In that month, too, the elder bushes are afoam with blossom, all the lane's length, and one recalls many a kindly superstition of the countryside touching the elder. Like the rowan, it is a tree of benison and all good luck. Its flowers are packed with honey for the hives; gathered fresh and made into an essence, they are good for the

Digitized by Google

complexions of Dales lassies that seem to need no further charm. Its berries make wine, held in great esteem.

One lingers on description of stream and lane, because the garden's roots are there—the roots of this special garden I have in mind. And it is only by starting at the roots that you understand the surface growth of anything.

A lawn slopes up from the stream and the wicket gate to a grey ancient house that was young, one surmises, about the time that Mary of Scots languished on the long, sick road to Fotheringay. The house is peopled by old memories and kindly ghosts that lie in wait along the corridors with whispered God-speed. Altogether, a house to inspire a garden that has answered the clear call.

As you come in at the main gate, you are aware only of a shady path, till on closer acquaintance the beginning of the rock garden shows itself. Shade-loving plants are there in their seasons. The primrose tribe thrives among the grey limestone rocks. So, later on, do the campanulas—the little creeping folk in front, backed by their taller cousins. Woodruff scampers in and out among the boulder crannies. Wild pansies lift their little elves' faces from unexpected corners.

The path winds into the open suddenly, across the house front with its long border strip of blossom, then dips sharply under a hillside that in itself is a rock garden of intriguing charm. Great boulders climb the hillside, and their crannies are filled with sun-loving things that sprawl and riot half over the rough bulk of their parent rock. The houseleek thrives there, and all its waxy-leaved brethren So do the rock roses, white and gold and salmon-red—and alpine broom, that flowers itself almost to death each year, but recovers gamely.

A second curve of the path brings you to yet another type of rock garden, stretching to the stream-bordered field beyond. This in turn merges into the striding pastures, coppice-dotted, and these into the high moors and the far, over-arching sky.

One of those upland pastures looks down on its own stone, brought here to make a home for the thrifts and saxifrages, the alpine wallflowers, the heaths, that in turn fling their blossoms in spend-thrift sheets of colour. London Pride is here in plenty, liking full sunlight as it loves equally the shade. So is a little friend with a name too long for her inches —Primula farinosa. We of the country name her mealy primrose.

Again the rock garden blends with its surroundings. Below there, where a strip of woodland guards the stream, forget-me-nots spread a blue, mystic haze under free-blooming honesty, a plant beloved in the Dale. A little earlier crimson saxifrage—in the rock garden here—was a joy with bloom. August, on the moors far up into the sky's rim, brings its own crimson glory of the heather. Seen from the garden, it is a patch no bigger than the saxifrage showed to onlookers from Lovers' Lane when it was in its pride.

All is in harmony, from garden to pasture lands and moor, as if the three were one. And this brings home again the certainty that in country gardens, with free room about them, rock spaces can wander anywhere, if placed by a hand that has served its apprenticeship of love, by a spirit that foresees in autumn how to plan for vagrant spring and golden summer.

In this garden of the Dale, you will find all manner of plants in what should be incongruous nearness. Willow Herb glows in crimson riot and in unexpected places. Sweet rocket—the wild phlox—makes a home where it lists. Marigolds will not be denied, when they choose to seed themselves in likely quarters, and flaunt their glowing blossoms to the sun.

Yet all is orderly. Once, in that garden, I walked with the builder of it, and with an ancient man who had been a gardener before Time, in its passing, supplied him with rheumatism and a crutch. His name was Aaron Waddilove, and seemed to fit him. He was so wise, so calm with quiet of the elder days.

"I can see you started by making your garden-paths first," he said. "You looked at all the twists of stream and pastures, and brought your paths into line, inch by inch and foot by foot."

"I did, as it happened. How did you guess?"

"Because they march with the lands outside. It couldn't have been done otherwise. Then you began to plant—good, honest roots. No fancy stuff for you because it happened to be rare."

Aaron looked up and down the garden, with a smile whose memory lingers with me to this day.

"What a muddle it might have been—and what a sheer joy it is," he said, lighting his pipe afresh. "It's the garden and you together—trusting each other. A garden knows her own, just as a woman does. And I'm glad to see you so free with your London Pride. You can never have too much of it, say I."

The spring gloaming surprised us as we lingered in the garden that would have been a dream if it had not been real. And everywhere, from moor to drowsing pastures, romance stirred vagrant wings. HALLIWELL SUTCLIFFE.

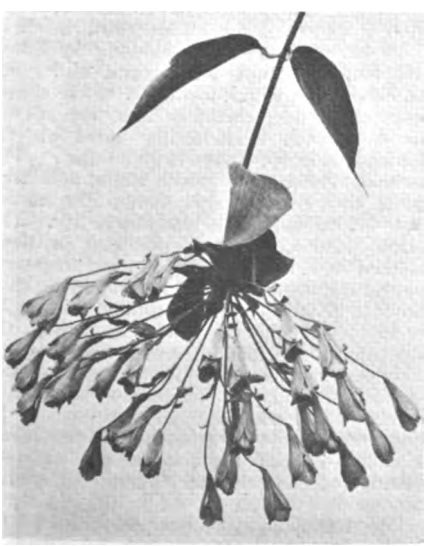
NOTES OF THE WEEK

TWO HYBRID BOMAREAS.

BOMAREA MATTHEWSII.

This plant was raised in the Glasgow Botanic Garden, and is the result of crossing Bomarea Carderi with B. edulis. When shown at the Fortnightly Show of the Royal Horticultural Society on October 20th, it obtained an award of merit.

It is a great improvement upon either parent and will, undoubtedly, prove a useful addition to the list of plants suitable for a cool greenhouse.



B. MATTHEWSII, WITH LONGER STALKED DULL PINK FLOWERS.

BOMAREA WHITTONII.

This fine hybrid was also granted an award of merit at the same fortnightly show at Vincent Square, Westminster. It is one of several that have been raised recently in the Glasgow Botanic Gardens, and is named in compliment to the late Mr. Whitton, Director of Parks and Gardens, Glasgow. The bell-shaped flowers are pinkish white, prettily spotted with chocolate. It is the result of a cross between B. edulis and B. Carderi, and will, undoubtedly, prove an acquisition to the greenhouse.

Bomareas are not so widely known as they deserve to be, especially when one considers how easily they are grown. All they need, if grown in pots, is a support for their long, twining stems, and a light position in a cool house. If planted in a border and the shoots supported on wires, they will amply repay the little trouble spent upon them by producing a succession of their drooping, bell-shaped flowers.

The genus contains about seventy or more species, but, alas! there are not more than the five following now in cultivation.

BB. Caldasiana, yellow, spotted red; Carderi, pink and green, spotted brown; edulis, pink, spotted brown; patacocensis, wine colour; Banksii, orange red, a hybrid raised in the Cambridge Botanic Garden, between B. Caldasiana and B. patacocensis. —E. H. BANKS.

THE LONG BELL-SHAPED FLOWERS OF B. WHITTONII.

Digitized by Google

AN INTERESTING BI-GENERIC HYBRID.

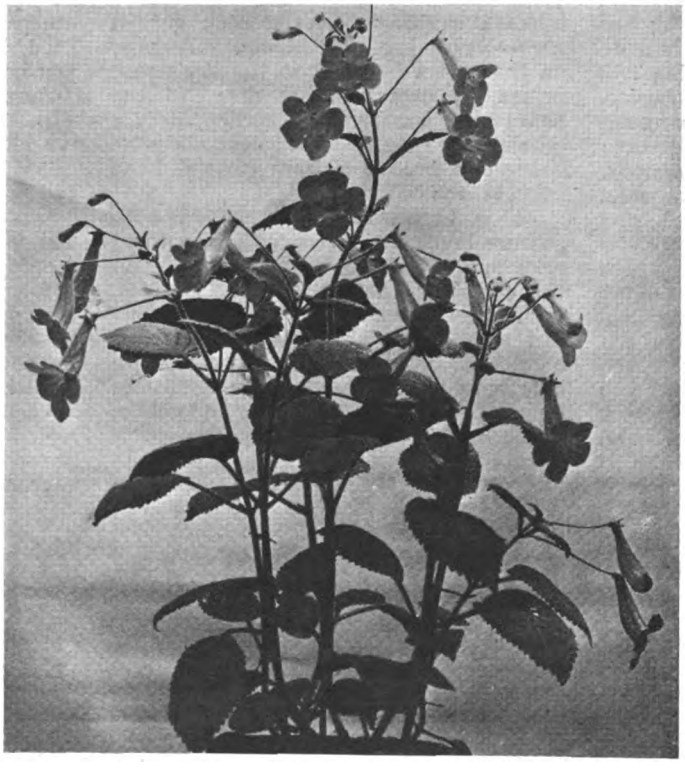
THE Natural Order Gesneriaceæ provides us with some of the best and most useful flowering plants for the embellishment of our plant houses. They are principally summer-flowering plants, but by careful cultivation a display may be had from April to December. Much good work has been accomplished by the hybridist, and this may be seen in the excellent strains of gloxinia (sinningia), gesnera and other plants of this family now available.

Mention must also be made of other useful, but perhaps less known, plants, such as tydaea, isoloma, nægelia, saintpaulia, achimenes and columnea. The introduction during recent years from Costa Rica of Columnea gloriosa var. superba and others of this genus are welcome additions to a race of useful and decorative plants. The accompanying illustration is from a a photograph of a new bi-generic gesnerad raised in the Glasgow Botanic Garden.

This interesting hybrid is the result of intercrossing Achimenes grandiflora with Gesnera zebrina, the latter being the pollen parent. The flowers were pollinated during the summer of 1921, and from the pollination five fertile seeds were produced and successfully harvested.

These seeds were sown early the following spring and placed in a stove house having a temperature of 65° to 70°, where they germinated in about three weeks. When large enough the seedlings were potted singly into 4in. pots and afforded all the light possible. Subsequent treatment was similar in every respect to that afforded to gloxinias, and by the end of August the first flowers appeared.

This newcomer, as may be seen by the illustration, bears strong evidence of gesnera blood in the broad leaf, which is covered with hairs of purplish metallic colour, and also in the tubular, gesnera-shaped corolla which has an orange coloured throat. After flowering the plants are allowed to ripen off and the root tubercles, which are similar to those of achimenes, are stored in a dry place for the winter.—B.



ACHNERIA "ST. MUNGO," A FINE HYBRID GESNERAD.

MILKWORTS FOR THE ROCKERY.

THERE are a few lovely little polygalas, flowering in spring, whose presence gives a charm of undeniable value to the rockery or rock garden, and which add immensely to the enjoyment it affords its owner and friends. Two of them have been in cultivation for many years, and their hardiness and the methods of culture have been fully tested. These are Polygala Chamæbuxus and its variety, P. C. purpurea. A later aspirant for our favour is called P. Vayredæ, and it is of great beauty, though not so suitable as the others for the colder localities of the British Isles. As a general rule, P. Chamæbuxus and its variety are quite hardy, but it has been found in some places in the north-west, where there is frequently much rain in late autumn and winter, followed by severe frosts with strong winds in late winter and early spring, that these exquisite polygalas occasionally succumb, if not in positions sheltered to some extent from bitter winds. But this is not by any means general, and is infrequent even in the district mentioned, so that those who wish to grow these lovely box-leaved milkworts need not hesitate to try them. Any ordinary soil, not too heavy, will suit them well, but I prefer loam and leaf-soil in a position not parched at any season and with a little shade, though they have been found to do well even in sun. P. Vayredæ should have a warmer position with a more porous soil and can stand more sun. Its distribution in gardens is not as yet very wide, so that its foibles have not been learned to the full. P. Chamæbuxus is a neat little plant with leaves like those of the box and has charming flowers of white and yellow. It is only 4ins. or 6ins. high and of rather spreading habit, if we may use this term as applicable to such a neat and non-aggressive miniature shrub.

Its variety purpurea is a still more exquisite plant with rather bigger flowers, and these are a combination of purple and yellow which harmonise so well together on the little pea-shaped flowers.

P. Vayredæ is a smaller and, if possible, a still more lovely little shrub. Its harmony of gold and carmine-rose presents a picture of the utmost charm, and, but for the slight doubt respecting its absolute hardiness, would have a widespread popularity. Many, however, may well take their chances of success and cultivate this shrub, which, like its allies, stands in the front rank of alpine flowers. Plants may be bought in pots for transplanting at any time.—S. ARNOTT.

THE ALPINE CATCHFLY.

THERE are some alpine flowers which ought to be in every garden where there is even only a miniature rockery and which, when seen either in small plants or in abounding masses, always delight the true lover of flowers. Of such is undoubtedly the exquisite alpine catchfly, Silene alpestris, which, though lovely in the extreme, has also the not-to-be-overlooked merit of cheapness, and, in addition, that of easy culture. It is an exquisite plant with narrow, glossy green leaves and an abundance of pure glistening white flowers with fringed petals. It is so easy to grow in light soil that its real likings are not considered, and it will thrive nearly anywhere. It loves not only a light soil, but it delights in a fair amount of moisture, and with this will grow and flower with greater luxuriance, particularly if the position is a cool one. There is a widespread belief that all alpines love full sun, but this is a mistake, and Silene alpestris is one of the lovers of coolness. There is a very charming double-flowered variety, S. alpestris fl. pl., and there is also said to be a pink one, found on the granite (the white one is a lime-lover), which is excessively rare. Propagate by division or by seeds in the case of the single form, but by division or cuttings only with the double one.—DUMFRIESSHIRE.

HARDY PRIMULAS.

IN large gardens and adjoining woodlands there is rarely much difficulty experienced in finding suitable quarters for the hardy primulas. In small gardens we may have these lovely flowers, too, if we study their requirements a little. There are many varieties of hardy primulas. Some are termed hardy, but require a little protection in severe weather, and the small cultivator should leave them out of his list. They all thrive splendidly in ordinary soils, but they are worth special mixtures if the very best flowers are to be obtained. I shall not easily forget the grand display of hardy primula flowers I saw last June in a large garden and woodland in the New Forest. For several years I have been privileged to inspect the groups of these plants, the flower-stems of many plants being 2ft. high and topped with huge trusses of richly coloured blossoms. The plants were grown in three different positions. A reference to them may be of interest and use to readers who are commencing the cultivation of these plants. At the sides of an ornamental sheet of water with other subjects, the primulas were luxuriating, their roots being permanently under water. In this case a fresh batch of young plants was raised and planted there annually. The next to claim attention were plants growing in colonies in slight depressions in the ground on a gentle slope having a due north aspect. These depressions—cups—in the ground collected moisture which was constant and just in sufficient quantity to maintain the plants in robust health. These were the plants having flower-stems 2ft. long. The third batch of plants were growing in almost pure leaf-soil, sand and gravel under oak and other trees which formed a wood almost clear of undergrowth. The aspect was due east, with a sheltering wood on the opposite side of the little valley. The primulas grew on a gentle slope, and here, again, the subsoil was constantly moist, while on the surface it was nearly dry. The plants were about half the size of those referred to in the north aspect, but they were healthy and flowered freely, and lived healthily throughout the winter months. In small gardens rock stones are a great help in the growing of the plants, and where suitable positions are available small colonies may be established and the necessary soil placed there. The compost should consist of well rotted leaf-soil, grit, the rougher pieces of charcoal from wood ashes and an equal quantity of good ordinary loam. Of course, the rooting medium should be of good depth.

The following varieties are suitable for both large and small gardens: Primula cashmeriana, P. c. alba, P. rubra, P. cortusoides, P. denticulata, P. d. alba, P. farinosa,

Digitized by Google

P. glutinosa, P. helvetica alba, P. sikkimensis, P. rosea for massing, P. viscosa and P. japonica hybrida. The latter are especially valuable for planting in naturally shaded,

A GROUP OF PRIMULA DENTICULATA ALBA.

damp positions and low down on rockeries. These will do for first planting and may be added to from time to time.—G. G.

A NEGLECTED AQUATIC.

THE water willow or swamp loosestrife (Decodon verticillatus), a near relative of the purple loosestrife (Lythrum salicaria), is a very common suffruticose plant in Massachusetts and is found southward to Florida and westward to the Mississippi valley. It is aquatic or semi-aquatic in its habits, favouring the margins of lakes and ponds, where it forms dense masses which, in early autumn, are glorious drifts of orange, scarlet and crimson. Intolerant of companions as a hermit, it fringes open waters ribbon-wise and spreading into broad bands crowds out all other plants. From the clumpy rootstock in the mud below, ascending shoots are upthrust which, arching somewhat and often whip-like at the ends, stand from 3ft. to 4ft. above the level of the water. These shoots for about a foot or more at the base are enveloped in a curious spongy mass of aerating tissue. The whip-like tip develops branches and puts forth roots when it touches the water or mud and thus a new plant is formed. The stem is angular, with the leaves arranged mostly in whorls of three; but towards the tip the arrangement becomes irregular and the leaves may be in pairs or scattered. The leaves in shape are oblong-lance-shape, pointed at both ends and short stalked, from 2ins. to 4ins. long and from ½in. to 1in. wide. From the leaf axils on the upper third of the stem arise sessile clusters, each containing from three to several slender-stalked flowers; the individual flowers are about 1in. across with five rose-purple pointed petals and stamens of unequal length. The fruit is a small dried capsule containing minute seeds. The flowers are not showy and during the spring and summer the plant is not particularly attractive, but at the approach of autumn what has been merely a pleasing fringe of green leafed stems arching and swaying in the breeze, becomes a blazing screen of colour.

The water willow is one of the earliest plants to assume autumn tints and no waterside herb or shrub excels it in brilliancy. Early in September I saw in the distance on the edge of a pond a fiery mass of scarlet which for the moment I thought was a profusion of cardinal flower (Lobelia cardinalis). Too late in the season for this plant to be in full blossom, I ventured across to find that it was the decodon decked in autumn robes, and a more brilliant spectacle of the kind I have never beheld.

Rich as the gardens of the British Isles are in plant material, not a few of the common plants of North America seem quite unknown to them. The subject of this note is a case in point. I do not find it in the Kew Handlists, and it is not mentioned by Bean in his "Trees and Shrubs." Nevertheless, it was one of the first recorded American plants. Ray, in his "History" (Vol. III, page 504, No. 9, 1704), mentions it under the name of Lysimachia purpurea Marilandica; Gronovius in his "Flora Virginica," 52, 1739, lists it as a Lythrum with opposite leaves and verticillate flowers and states that it was collected by Clayton. Linnæus in 1753 named the plant Lythrum verticillatum; in 1791 it was made a type of a new genus (Decodon), by Gmelin. Under Linnæus' name it is said by Aiton ("Hortus Kewensis," Ed. 2, III, page 150, 1811), to have been introduced into cultivation in 1759, so apparently it has been lost to British gardens. New England winters are more severe than those of the British Isles, where it would seem there is no reason why this attractive plant should not flourish. In water-gardening for the edge of ponds it is a most desirable plant and to visitors from Europe who see it growing wild in Massachusetts in September its appeal is irresistible.—E. H. WILSON, *Arnold Arboretum.*

THE PROPHET FLOWER.

WE need not believe the tales associated with them, but plants of legendary lore appear to have about them some special attraction for us, and those who have dabbled much in plant lore and legends, find in these flowers a pleasure not always justified by their outward beauty. But with the prophet flower, Arnebia (or Macrotomia) echioides, there need be no reservation whatever. Apart from the interest of the legend that Mahomet left the marks of his finger tips upon the flowers, this plant is of high charm indeed, and is always appreciated in the rock garden or even the border, where it may be planted with advantage near the front. It has narrow, rough-looking foliage and forms good tufts where it is happy, giving us from June onwards for some time clusters of numerous open yellow flowers marked with the spots alluded to in the legend. These are black when the flowers open first, but gradually fade away to almost lemon yellow. At first they look sharply in contrast to the soft pleasing yellow of the petals, but afterwards they seem to be more in unison with the general *motif* of the plant. As the flowers open in succession the individual blooms show the transition of colour of these spots at all stages.

This prophet flower is by no means difficult to cultivate in this country, and appears to be very hardy, although it is said to come from hot plains in northern India, where it grows in stiff soil, and stands a considerable amount of drought. With us it would seem to like a dry soil, inclined to lightness and well drained. It is propagated by cuttings or by seeds, but these are seldom offered for sale. Some seasons I succeeded in saving a few seeds, but they are not freely produced in this country, I think. This is one of the best rock garden plants we have and one which can be recommended with every confidence.—S. A.

THE WATER WILLOW (DECODON VERTICILLATUS) GROWING BY THE WATERSIDE IN THE ARNOLD ARBORETUM.

THE TREATMENT OF INDOOR FRUIT TREES IN EARLY WINTER

THERE is much important work to be done in connection with inside fruit during the early winter. Ripe grapes, which are required to hang as late as possible, must receive constant attention in the way of judicious ventilation on fine days, and fire heat when necessary to assist in maintaining a dry atmosphere. Vines from which the crop has been gathered and the leaves have fallen, should be pruned and cleaned. Peach, nectarine and fig trees will require attention, and where orchard-house trees, such as apples, pears, plums and cherries, are grown, these too should be overhauled. Even though it may not be intended to start any of the above kinds before the New Year, it is well to feel that such work is done and everything in readiness for a good start.

By the time mentioned. no doubt, in some gardens, forcing of some of the above will have commenced. Very early forcing, however, is much less practised than was the case at one time. It is all to the good of the trees that they are not unduly forced. By allowing them to come along more naturally with the aid of more and stronger sunlight, the fruits are invariably of superior flavour.

When vines are grown in a house by themselves, or with only a few well chosen companions, they can be kept in good health for an indefinite time. When, however, the vines are in perpetual association with a general collection of plants, such as one occasionally sees in the amateur's greenhouse, the question is very different, and pests sooner or later make their presence felt and are most difficult to eradicate.

Mealy bug—the worst of all pests of the vine—frequently gets a footing through having been introduced on other plants. Whether pests have given trouble during the season or not, the vines should be stripped of loose bark, cleaned and thoroughly scrubbed with a good mixture such as Gishurst Compound—an old but reliable insecticide. Previous to this the vines should have been lowered from the rafters and pruned, cutting back the laterals, current year's wood, to two eyes, except in the case of a few varieties such as Lady Hutt and Cannon Hall, which should not be pruned so severely.

Where the roots of vines are growing in outside borders, the latter must be protected from heavy rains by means of corrugated iron sheets or glass lights.

If for any reason it is thought desirable to examine the borders, whether inside or out, this should be undertaken as soon as possible.

Borders properly made in the first place will go on for many years without further attention other than an annual top-dressing of good soil. The latter is best given after the house has been cleaned and vines tied in position. A few inches of the top soil is pricked up and removed and replaced with the very best loam to which has been added lime rubble and bone-meal. In the case of old vines some decayed farmyard manure could be added.

Peach trees will also require attention. Defoliation will take place according to the length of time the trees have been in active growth. It is wise to gather the fallen leaves frequently, as oftentimes red spider—the worst pest of the peach—has been troublesome, and the removal of the leaves would do something to rid the house of this pest for the following year.

When the leaves have all fallen the house should be thoroughly cleaned by washing glass and woodwork and white-washing the walls with hot lime; this applies to all fruit houses. The trees should then be pruned, cleaned and tied back in position, unless the roots need attention, in which case the tying in should be deferred.

The pruning will depend largely on the amount of summer pinching done and on the age and size of tree.

If a tree has not covered its allotted space the extension leaders must be continued. A well balanced tree trained to the usual fan shape should have about eighteen main branches, nine each side of the centre, to form the framework, from which the fruiting wood is produced annually. The peach and nectarine fruit on wood of the previous year's growth, and sufficient of this should have been retained during summer to take the place of old fruiting wood, which can be cut back at any time after the crop has been gathered.

The final pruning is often left till the tree is free from leaves. Well ripened shoots are necessary to produce good fruit, and these, after being washed, should be tied in parallel to each other, never overlapping, at about 4ins. to 6ins. apart. Young trees before coming into bearing, and occasionally after, need root restriction, and this is best done by carefully lifting the tree, shortening any strong shoots and replanting, taking the opportunity of adding some good loam and lime rubble around the fibrous roots and ramming firmly. A good watering when the work is completed is advisable to settle the soil.

In the case of older trees in full bearing, a portion of the top soil should be removed and fresh added, the richness or otherwise being based on the condition of the trees. If they are in the habit of annually carrying good crops of fruit, some decayed farmyard manure should be added to the loam, together with wood-ash and bone-meal. A word of caution is necessary about the moisture of the border at this time of year. On no account must it be allowed to become very dry. Mistakes in this direction have often resulted in wholesale bud-dropping in spring and a total loss of crop.

If new trees are to be planted, this is best done as early in autumn as possible. In this connection it is well to remember that, if obtainable, quite strong and large trees can be safely transplanted and a crop obtained without the loss of a season.

Peaches and nectarines can, of course, be very successfully grown in large pots or boxes. I have seen splendid crops of fine fruit grown in strong boxes which had previously done duty as packing cases for lilium bulbs imported from Japan. The trees, trained fan-shape, made fine manageable specimens.

When grown in these boxes it is not usual to shift them into others of larger size, but annually or biennially the trees need to be carefully turned out of the boxes, and the balls of soil slightly reduced, cutting off any strong roots at the same time.

Rich new soil must replace the old, and this must be firmly rammed between the ball of soil and edge of box.

Figs grow and fruit well in comparatively small pots. Fruiting trees need an annual shift into slightly larger pots, and this may be done at any time in autumn with trees to be started in the New Year.

A suitable compost would be one of strong loam, a small portion of decayed farmyard manure, bone-meal and lime rubble. Very firm potting is essential. Until ready for starting in heat, all kinds of fruit trees ought to be kept as cool as possible.

ARTHUR J. COBB.

CORRESPONDENCE

THE BREAKING OF TULIPS.

SIR,—I have read Mr. Needham's able article on the breaking of tulips with keen interest. Probably no one is better qualified to deal with the past or recent history of this ancient garden flower, or more fully versed in its behaviour under cultivation. As he reminds us, all tulips break sooner or later, though no definite rule can be laid down as to the period when this will take place. Centuries of careful culture and close observation have failed to elicit any clear reason for, or to suggest an infallible means of either hastening, delaying or preventing, the change. It is, however, tolerably certain that once it has taken place, complete and lasting reversion never occurs. The old florists were tireless in trying possible expedients to accelerate it, and so earn distinction by presenting some new beauty of flame or feather to an admiring brotherhood of fanciers; and their successors—no less enthusiastic, if fewer in numbers—still welcome a "good break." Yet "one man's meat is another man's poison," and to the commercial grower of the popular Darwin and cottage varieties breaking is a matter of grave concern, causing serious financial loss; hence Mr. Needham's timely appeal for research on scientific lines.

I am inclined to think the explanation of the "break" lies not in any special character of soil—light or heavy, rich or poor—nor in any extreme of climatic conditions. Neither do I regard it as a consequence of some mysterious disease, either air or aphis-borne. Rather I conceive it to be the cumulative result of centuries of an intensive method of cultivation with two main objects, *viz.*, the production of large bulbs, and the quickest possible increase of selected varieties. Be it remembered the tulip is the oldest cultivated bulbous plant of which we have records. It must have been assiduously

Digitized by Google

grown in the East long before its introduction to Europe in the middle of the sixteenth century, and probably during the whole of that period it has been subjected, as in the present day, to annual lifting, drying off, storing and replanting. Small wonder, then if under such conditions it has acquired by inheritance a characteristic not found in any known truly wild species of tulip. While I cannot believe we shall ever entirely eliminate "breaking," it seems quite likely that occasional periods of cessation from the usual annual procedure might result in lessening or delaying it to some extent. May I suggest as an experiment the planting of sound breeders where they can remain undisturbed for three or four years—either English florists', old Dutch, Darwin or cottage varieties. The stock when lifted will, of course be small in size but enormously multiplied. If then planted out and treated under the usual nursery routine, it is my firm belief that during several ensuing seasons few or no breaks will appear. If warranted by results, it would be a simple matter to keep relays of each kind constantly "recuperating," and this would become a part of normal nursery practice.

The matter is so important to the bulb-growing industry in this country that it should be taken seriously in hand.—CHAS. J. FOX, *Moseley*.

CHRYSANTHEMUM SPORTING.

SIR,—I have had a dull pink variety for many years, and have wished for some others as hardy and prolific. This year a stem has come up with most attractive bronze yellow flowers on it. I have marked it and hope to get some basal cuttings from it, but I still wish for white, which is always in demand. Perhaps some readers of THE GARDEN may have found white sports.—J. H. POE, *Nenagh*.

HELIANTHUS SPARSIFOLIUS.

SIR,—I fully endorse the opinion given by the Rev. J. Jacob, in one of your recent issues, (page 583) as to the beauty and value of H. sparsifolius. I prefer to call it by the old name, as the newcomer, H. Monarch, proved to be identical in all respects—there was no difference whatever apparent when grown side by side. As to the origin of H. sparsifolius, this is said to be the result of a cross between the perennial H. rigidus and H. annuus californicus, and the unpleasant trick of dying off sometimes is no doubt due to the annual blood from the latter. Its worst enemy is stagnant moisture in winter, and in a well drained sandy place it has grown and flourished for years here without protection in winter. A good scheme is to lift a few plants in autumn and keep them during the winter in a cold frame, thus giving a fresh stock in hand in case some plants might succumb. The flowers appear on strong rigid stems during August, September and the greater part of October, and last a considerable time in water.—TH. HOOG, JUN., *Haarlem*.

MYRICA ASPLENIFOLIA.

SIR,—With reference to the article "Shrubs in Argyllshire," in the issue of THE GARDEN of October 31st, which gives a selection of rather tender shrubs suitable for the mild climate of western Scotland, I would like to say that the interesting little Myrica (Comptonia) asplenifolia is really absolutely hardy, and easily bears the inclemency of rough winters on the Continent. In neither a sheltered nor even a sunny position it survived the exceptionally hard winter of 1923, in which we had thirty degrees of frost; such a low temperature is doubtless unknown in any part of the British Isles. If there are really failures with that little shrub in some parts of Great Britain in the open, I think that it may be rather due to the fact that it dislikes lime, in the same way as its near relatives M. Gale and cerifera. The worth and charm of the whole of that kinship is their glossy, healthy leafiness, lasting here mostly till January.—DR. FRITZ LEMPERG, *Hatzendorf, Styria*.

GRAPES IN A COLD-HOUSE.

SIR,—I am enclosing a photograph of grapes grown in a cold vinery, which I thought might prove of interest to readers of THE GARDEN.

The variety is Muscat of Alexandria, and the berries are perfectly finished, although the season has not been of the best for ripening grapes without the aid of artificial heat.

Varieties grown in the same house are Black Hamburgh, Madresfield Court, Black Alicante and Alnwicke Seedling, and the vines are planted in an outside border. Ferns and flowering plants are grown in the house all the year.

The first two years I took charge of the gardens, the vines, although treated in the ordinary way, were a failure. The foliage and bunches being covered with mildew. I then treated them as follows, and for four years the vines have carried heavy crops, and no signs of mildew have appeared.

After pruning the rods are cleaned of all loose bark and dressed with a mixture of pure "Abol" and powdered sulphur, about half of each. This mixes to the thickness of ordinary paint, and is painted on with a brush. The vines are never syringed and unless the weather is very cold, the top ventilators are never completely closed. The house is kept as dry as possible, and when the vines are in flower the bunches are gone over each day with a rabbit's tail to distribute the pollen. The prevailing idea is that muscats require a lot of heat to bring them to perfection. Some of the bunches weigh over three pounds and are well finished. Therefore it appears that this grape may be grown with success under much cooler conditions than is generally accepted.—A. G., *Walmer*.

A FINE CROP OF MUSCAT OF ALEXANDRIA GROWN IN A COOL VINERY.

VIBURNUM CARLESII.

SIR,—The only honest course for one who has badly blundered is to acknowledge and apologise; wherefore, having recently in your columns stated that V. Carlesii is practically evergreen on the west coast, and having returned home to find all our plants of that species nearly bare of leaves, I confess that I was utterly wrong. It is undoubtedly deciduous; but whereas Mr. Hillier described this fine species as flowering before the leaves, here the fresh foliage comes with the flowers, as is shown in a faithful drawing made last May.—HERBERT MAXWELL, *Monreith*.

COLOUR VARIATION IN HYDRANGEAS

SIR,—I have been greatly interested in Mr. H. Avray Tipping's account of his hydrangeas in Monmouthshire (November 7th, page 625). Here in West Somerset one finds the same extraordinary variation in colour in different plants of the same variety growing perhaps only a few feet apart. This is particularly evident in plants grown in ordinary garden soil, and it seems well-nigh impossible to account for a pale blue and a dull rose form growing side by side on the ground of soil alone causing the variation. If cuttings are taken from the pale blue form there is no certainty that the resulting flowers will turn out to be the same shade as the parent plant, even if grown in the same garden. No doubt certain varieties are more stable than others, and if one finds the first variety attempted fails in colour, it is well worth trying another variety. Most people prefer a good blue to any other shade, and in many gardens it seems almost impossible to obtain it. Here, in a lime-free loam with a liberal addition of peat, I grow two varieties which come as beautiful a blue as one can possibly desire. The first variety to bloom is H. hortensis rosea. I believe it is of Japanese origin, and was introduced by Maries many years ago; the leaf is smaller and more deeply veined than in other varieties, and the trusses of flower are not so immense as most of the modern varieties. The colour is almost that of Gentiana acaulis. The other variety is Radiant, said to be a good crimson, but here a remarkably fine true blue; as it begins to flower when hortensis rosea is going over it forms a valuable succession. I feel sure that peat plays an important part in bringing the blue shades to perfection; some of my plants were put in a nursery bed with no peat added to the loam, and they flowered an unpleasant pinkish lilac colour. In another garden in this district where the soil is mainly peat the ordinary H. hortensis are all blue, though not such a fine shade as the two varieties referred to above.

Digitized by Google

There is a very distinct variety of H. hortensis known as nigra (or cyanocladon), in which the stems are a glossy black; unfortunately, the flowers (in this garden, at any rate) are a rather poor pinkish shade, but the peduncles of the individual flowers are of such a charming crimson that it is worth some effort to induce the colour of the flowers to improve by giving it a different soil. I intend moving my plant to a peat bed where possibly it may turn either blue or a better pink.—N. G. HADDEN, *West Porlock, Som.*

ERITRICHIUM NANUM.

SIR,—I was very interested in a letter from Mr. Ascel Olsens in your issue of November 14th, in which he gave his impressions of Eritrichium nanum. I send you a photograph I took of it this summer in one of Farrer's favourite haunts on the heights above Mont Cenis.

I must shamelessly admit I am a heretic: I do not worship this plant. My own impression is that the spell of Farrer's wonderful pen, and perhaps also the spell of the mountains, have led people to overrate it. Granted it is a pretty little plant; but even if one could establish it in this country, I could name quite fifty alpines which I consider more beautiful. It is, after all, a dwarf forget-me-not with the blue flowers of its race and the peculiarity of the forget-me-nots of running into dull pink colours sometimes. Its foliage is compact and fluffy, but many alpines we grow in our rock gardens can boast of this. I think that much of the cause of its deification lies in the fact that away from its native haunts it is intractable. I wonder how long it would take this wave of enthusiasm to spend itself if Eritrichium nanum could grow and seed itself in our gardens like Erinus alpinus.—A. GAVIN JONES.

GARDEN RUBBISH.

SIR,—As the efficient disposal of garden rubbish is a problem of great interest in horticulture, may I add a modest contribution in support of the "Pyrford" method?

When visiting Pyrford Court Gardens in June last, among the many interesting items it was my privilege to witness this means of "conversion" of garden rubbish which Mr. Auton so clearly advocates.

From this method of controlled decomposition of garden rubbish, the residue seemed to me in no way impaired, but as matter having great potential mechanical and manurial values in a suitable condition for incorporating with garden soils.

That it has this value is amply testified by the results in quantity and quality of crops produced in the gardens at Pyrford Court.

Truth to tell, I doubted that such crops could be produced from such a soil with only converted rubbish and crude chemicals as the staple element of production, and spent some time in seeking a refutation of the statement, but found none.

This method appealed to me strongly as a really efficient means of putting to a practical use material of great manurial value which in most cases is considered a nuisance and "dumped" in any convenient out-of-the-way place, often to become a heap of putrefaction and a breeding ground for all fungoid and insect pests peculiar to a garden.

Nor do I think the "smother fire" or "incineration" method of treating garden rubbish a very great advance on the "dumping" system. This entails a vast amount of labour that can ill be afforded, and a serious loss in material of high nitrogenous and phosphatic value, although it gives in return a small quantity of potash that is rarely put to the best use.

Besides, such methods, to be useful, must be continuous, and then they become an annoyance in the neighbourhood.

To me, it seems that, with the same amount of labour and time, Mr. Auton attains all that is good in the scheme outlined by Mr. Macself, minus its disadvantages, plus a great saving of valuable material, of which the extract of gas is not the least.—WM. MCCARRELL, *Doune, Perthshire.*

SIR,—It is not clear from Mr. Tomalin's note (page 634) to what department of the garden he advocates the application of raw garden rubbish as manure. If it is for culinary or fruit crops, I am not competent to offer any opinion upon his practice; but I should not care to enrich a permanent flower border with "cabbage stalks, dead leaves, mown grass, etc." This may have good results in an alkaline soil—*i.e.*, one based on chalk or limestone; but applied to a cool, acid soil it would be sure to produce fungus in variety. Moreover, in cultivating flowering plants one does not want the soil to be uniformly rich. What suits a peony or a kniphofia would be the reverse of favourable for a dianthus or Lilium regale.

ERITRICHIUM NANUM ON THE HEIGHTS ABOVE MONT CENIS.

Those who have command of a supply of peat may have noted that, when properly treated, it enriches the soil to which it is applied as surely as leaf-mould does; but, unlike leaf-mould, it harbours no slugs or injurious insects, and is quite free from all vegetable seeds, except heath and rushes; nor does it afford a nidus for fungus. But it must not be applied raw. Freshly dug out of a peat moss it is surcharged with humic acid and if used in that state will prove injurious, and even fatal, to many fine plants. To make it safe for use either in the border or the potting shed, it must be thoroughly pulverised, passed through a coarse riddle and exposed to sun and weather. It then forms a clean and nutritious ingredient in a compost. Seedlings appreciate it highly, fixing their rootlets in its particles just as they do in leaf-mould. It is true that Mr. E. H. Wilson, whose intimate acquaintance with lilies entitles him to the confidence of all those who deal with that capricious genus, condemns the use of peat in their cultivation:

"All lilies," he says, "love leaf-soil, but a great many detest peat. I have seen L. Henryi grow 10 feet high in loam and leaf-soil, and continue to thrive for many years. I have seen this lily disappear completely in two years when planted in pure peat." ("The Lilies of Eastern Asia," page 4.)

Granted; but I am not advocating pure peat for any plant—not even rhododendrons. To enrich loam and gravelly or sandy soil I consider it as valuable as leaf-mould, and preferable, in that one does not convey with it the eggs of slugs and other subterranean robbers.

Before passing from peat, may I mention another form in which it is invaluable to amateur gardeners, namely, Sphagnol soap. Nothing I have known removes soil so quickly and smoothly from the hands as this soap, which derives its virtue from peat.

Wood ash is another fertiliser whereof the merit does not seem to be sufficiently esteemed; at least, one often sees a heap of it neglected and left to be soaked with rain, which washes out the potash, its most valuable ingredient and highly soluble. It is specially stimulating to bulbous and tuberous plants, as appears from the following note by Mr. Carl Purdy upon the effect of a forest or brush fire in California:

"In nearly every instance our Erythroniums are wild in brushy or wooded regions and in uncultivated areas, where during our dry summers brush or forest fires are common. Before a fire, I have often seen Erythronium californicum growing in brush lands to a height of six or eight inches, with but a single flower. After a fire it may be sixteen inches or as much as two feet high, with from four to sixteen flowers." ("Flora and Sylva" Vol. II, page 251.)

Finely sifted wood ash, with chips of charcoal among it, may be used with advantage in planting bulbs of all kinds; but the potash will be washed out of it before it takes effect as a fertiliser, and a fresh application should be made after growth has started—HERBERT MAXWELL, *Monreith.*

TWO GOOD GARDEN SHRUBS.

SIR,—I am very glad to see in THE GARDEN for October 31st that attention is drawn to two very beautiful garden shrubs that have been much neglected. I first saw Erica australis var. Mr. Robert at Kew in April, 1922, and was much struck with its beauty, and since then have watched for its appearance in some nurseryman's list, but up to the present have been disappointed. The other one is Arbutus Unedo var. rubra (or Croomei), which when flowering well is a wonderful sight on a sunny October day. This I have also tried to get, but have had no success. It is to be hoped now that these two scarce shrubs will become available for general garden planting.—R. B. COOKE.

CLIMBERS FOR WALLS.

SIR,—The following experience with climbers for a north and south aspect respectively may be of interest to readers. Four plants of Tropæolum speciosum were obtained in pots in November last and planted out against a north wall. The soil is a shallow loam on gravel, and as the house had just been built there was a certain percentage of builders' rubbish in the soil. During the hot spell in June each plant received a 2-gallon can of water every four or five days, and water has been given freely all the summer. The growth has been remarkable, one shoot making 26ins. in sixteen days. The plants were trained up twine, 8ft. 6ins. in height, five strings about 4ins. apart to each plant. Two Pyracantha Lalandei have also been planted against the wall, so that in a few years it is hoped to dispense with the twine.

For clothing an oak trellis arch, 11ft. high by 9ft. wide and 3ft. deep, over a French door facing due south, two Dutch honeysuckles were chosen on the advice of THE GARDEN. Both honeysuckles have reached the top of the arch and are clothing it rapidly, with sweetly scented bloom.—W. F. NEWMAN.

LATE AUTUMN AT VINCENT SQUARE

THAT we have arrived at the dead season of the year was fully evident at the Royal Horticultural Society's Hall on November 17th last, on the occasion of the ordinary fortnightly meeting of the Society. The floral exhibits were few, consisting chiefly of begonias, chrysanthemums and carnations, and the hall, in consequence, had a distinctly empty appearance, which was made the more noticeable by the poor attendance. Fruit was represented by two exhibits, one arranged by Messrs. George Bunyard, and the other an exceedingly fine representative collection staged by the Hon. Vicary Gibbs. The quality, size and colouring of the apples especially were outstanding and reflected great credit on Mr. Edwin Beckett. As with shrubs and vegetables, Mr. Beckett certainly excels in the growing of fruit.

A very fine collection of winter-flowering begonias was staged by Messrs. John Peed and Son. The bright, yet soft and delicate, colouring was most marked in the hall, devoid of its usual gay tones. The plants themselves prove that they are indeed most effective for interior decoration during the winter months. The varieties which were staged showed their profuse flowering qualities and delicate shades of colour to the full. Among the varieties we noted the following: Eclipse, with beautiful salmon red flowers of a semi-double nature and set off to advantage by the glossy green foliage; Exquisite, bearing fine sprays of blush to deep pink single flowers, is a handsome variety; and Optima, which appears wonderfully free flowering, carrying abundant blossoms of a rich deep salmon colour.

Several good exhibits of chrysanthemums and carnations produced bright splashes of colour which relieved the dreary and otherwise barren look of the hall. The three well known carnation specialists staged representative collections. Messrs. Allwood Brothers showed carnations of various types, and Messrs. Stuart Low exhibited a large number of good blooms. On the stand of the latter firm, Lady Hindlip was an attractive variety; Sir Philip Sassoon, a beautiful deep crimson, and Eileen Low, the best of pinks, were also most noticeable. Mr. C. Engelmann had two new seedling carnations which he will put into commerce next spring. One was a bright red named Rouge, and the other an attractive pinkish red variety overlaid and flaked with deep red.

Mr. H. J. Jones had a large collection of chrysanthemums of all types admirably displayed. Many huge Japanese exhibition varieties were shown, including immense heads of the varieties Majestic, Queen Mary and Mrs. R. C. Pulling. The condition and shape of the blooms exhibited by Messrs. Keith Luxford were excellent. Ethne, Everbright and Commandant were three splendid new varieties. Mr. A. G. Vinten had an attractive collection of some of the best of the border chrysanthemums, including such fine mid-season varieties as Golden Wonder, Gloriosa, Golden Marvel, and Aldyth.

Tender and hardy shrubs were shown by Messrs. Stuart Low and Messrs. L. R. Russell. The latter firm exhibited variegated ivies, such as the large-leaved Hedera dentata variegata, also Juniperus pachyphlæa and J. Bermudiana, well berried sprays of Cratægus Pyracantha Lalandei, and several other interesting shrubs. A few attractive acacias covered with masses of yellow bloom were seen on the stand of Messrs. Stuart Low, the most conspicuous being A. platyptera, A. Baileyana and A. armata. Two excellent new apples, George Carpenter and Victory, were shown by Messrs. Brinkman Brothers. St. Brigid anemones were exhibited by Messrs. Reamsbottom; Helleborus altifolius by Mr. Scarse-Dickins; and an interesting collection of photographs of gardens, designed by the garden architect Mr. Percy S. Cane were on view.

NEW AND RARE PLANTS.

AWARDS OF MERIT.

CHRYSANTHEMUM CLIO.—Shown by Mr. H. Shoesmith, jun., Woking. Described under "New Chrysanthemums."

CHRYSANTHEMUM CRIMSON DAWN.—An excellent single variety bearing well-proportioned flowers. The ray florets are of a dull deep crimson colour and radiate outwards from a fairly large yellowish green eye. The florets are daintily reflexed. Shown by Mr. J. Shoebridge, East Grinstead.

CHRYSANTHEMUM ENTON BEAUTY.—Shown by Mr. W. Hall, Witley. Described under "New Chrysanthemums."

LEONOTIS LEONURUS "THE WARREN" VARIETY.—Flowering sprays of this fine winter-blooming rather tender shrub were shown. The flowers are most distinct, being of a bright orange colour and very hairy. The corolla is three times as long as the calyx, which is rather arched. The flowers are borne in dense whorls from which arise two opposite lanceolate leaves. It is a most ornamental shrubby perennial and will be found exceedingly valuable for winter decoration. Shown by Mr. E. M. Preston, The Warren, Hayes.

GALANTHUS BYZANTINUS NOVEMBER.—An early-flowering form of this fine snowdrop which in no way appears to differ from the type, save that it flowers much earlier. The flowers were borne in some fine spikes and may have been a shade smaller than in the type. It is an exceedingly graceful and handsome species. Shown by Mr. Charles T. Musgrave, Godalming.

ORCHIDS.

AWARDS OF MERIT.

CYPRIPEDIUM BALDUR MAGNIFICUM (G. F. Moore × Niobe).—This elegant hybrid is a marked improvement on the well known Cypripedium Niobe. The dorsal sepal is flushed with rose and has a pretty venation of deeper rose colour over its whole surface; the petals are broadly crisped on their upper margin, tinged with reddish brown and marked with lines of a darker colour; the labellum well proportioned and of mahogany red. Shown by Lieut.-Colonel Sir George Holford, K.C.V.O., Westonbirt, Tetbury, Glos.

BRASSO-CATTLEYA ROSITA (C. aurea × B.-C. Ilene).—One of the prettiest of the Brassavola hybrids, the large flower being of rose pink colour, the expansive labellum having an outer zone of dark purple, and with the inner area bright yellow; the sepals have a marbled appearance produced by the yellowish ground colour showing through the rose pink. As in the majority of these hybrids, the labellum is effectively fringed. Shown by Messrs. Stuart Low and Co.

CYPRIPEDIUM ROSALIND (Niobe × Reginald Young).—A fine addition to the Niobe section of cypripedium hybrids. The dorsal sepal is prettily marked with purplish venation and dotting; the petals are yellowish, but much covered with dark longitudinal lines and spotting; the labellum somewhat roundly formed and tinged with mahogany red. The influence of C. Fairrieanum, derived from the Niobe parent, is clearly visible. Shown by Messrs. Sanders, St. Albans.

NEW CHRYSANTHEMUMS.

The Floral Committee of the National Chrysanthemum Society considered the merits of a large number of new varieties on Monday, November 16th, and awarded first-class certificates to the following:

AJAX.—A superb Japanese variety which has all the attributes of a first-rate exhibition bloom. It is a very large, beautifully formed incurving variety with broad florets which are lightly flushed with pale carmine on the surface and coloured bright yellow on the reverse. Shown by Mr. H. Shoesmith, jun.

CLIO.—This is a Japanese variety of what is now known as market size. The blooms are very shapely and of most uncommon and fascinating colouring, which, by daylight, is a delightful rosy puce and, under artificial light, becomes a fascinating bright rosy terra-cotta. Shown by Mr. H. Shoesmith, jun.

ENTON BEAUTY.—A valuable variety of good decorative size and rich velvety crimson colour, lightly touched with maroon. Shown by Mr. W. Hall.

JESSIE MCNAB.—A large single possessing several rows of bright canary yellow florets, attractively rolled at the tips. Shown by Messrs. Keith Luxford and Co.

MRS. F. BRILL.—A large single of deep rose pink colour heavily overlaid on white ground except around the disc where it forms a white zone. Shown by Mr. G. Carpenter.

R.A.—A fairly large incurved variety of value for decorative purposes rather than the show board. The broad florets are of rich yellow colour, and there is a bronzy glow in the heart of the flower. Shown by Messrs. Cragg, Harrison and Cragg.

GARDEN TECHNIQUE

Notes on the Technical Side of the Garden and the Cultivation of Plants.

FLOWERS

CULTIVATION OF SWEET PEAS.

I AM well aware that when one's soil is in "good heart," just digging it over in the autumn about a foot deep and using no manure whatever will often result in a wealth of good blooms for beautifying the garden and home, but by adding a dressing of animal manure the quality of the blooms will be doubled or trebled. Trenching the ground from 2ft. to 3ft. deep will give one still better sweet peas; indeed, trenching is quite necessary should one wish to exhibit successfully in keen competition. Even when the winning of prizes is not one's objective, a fairly elaborate preparation of the soil will be found more than worth the extra labour and expense involved. I will, therefore, describe the methods adopted in exhibition culture, leaving my readers to modify or amplify them as circumstances permit.

The choice of the most suitable plot or site for the sweet pea in one's own garden is not unimportant. It should be chosen carefully, with one eye, so to speak, on the requirements of the plants during their flowering period. In the first place, it should be open to the sunshine all the day, unshaded by trees or buildings, have a good depth of soil, and should not be drained by the roots of large trees. On the other hand, soil which is liable to become waterlogged as a result of excessive rainfall or through watering and feeding, should be avoided, while it will be found very convenient, later on, if it is situated near the available water supply and sheltered somewhat from the usual direction of the wind.

Digitized by Google

Although perhaps of no great importance, all these little points are, nevertheless, well worth taking into consideration.

On heavy land with a clay sub-soil the ground is best trenched all over the entire plot, otherwise the trenches simply act as catch-pits for surface water, and "bud dropping" or other more serious ills may result. If this is not convenient, take out trenches about 2½ft. wide and 2ft. or 2½ft. deep, if possible running from north to south, allowing at least 2ft. between the edges of each trench. The untrenched portion can then be worked the following season, thus ultimately enriching and moving the whole plot in two years. The usual procedure is to throw out the top 10ins. or 12ins. on one side of the trench, and the second layer on the other. Then break up the bottom roughly, mixing in a dressing of animal manure, or on soils likely to become waterlogged throw anything into the bottom that will act as drainage, such as crocks, stones, hedge clippings, or any garden refuse.

Before proceeding with the actual method of trenching, I should like to say a few words about manures. In the first place, those of an organic nature are to be preferred to chemical fertilisers. Where horse and pig manure for the heavier soils and cow or sheep for those on the lighter side can be obtained, there is no need to bother much about any other fertilisers. It is, of course, quite useless to incorporate anything of a quick-acting nature, or its benefit will be wasted, rinsed away by winter rains. Rather mix in manures which will disintegrate comparatively slowly, as animal and most other organic manures do. Bone meal and basic slag are good, so are wood ashes for the phosphates they contain. Poultry and pigeon manures are stronger and quicker acting than farmyard manures, but are quite suitable if used sparingly when preparing the soil. I should, however, regard them as more useful for feeding purposes when applied as top dressings during the flowering period. Sometimes it is impossible in semi-suburban and other districts to obtain good animal manure, and in such cases I recommend a mixture of leaf-mould (or spent hops) and bone meal (or meat meal).

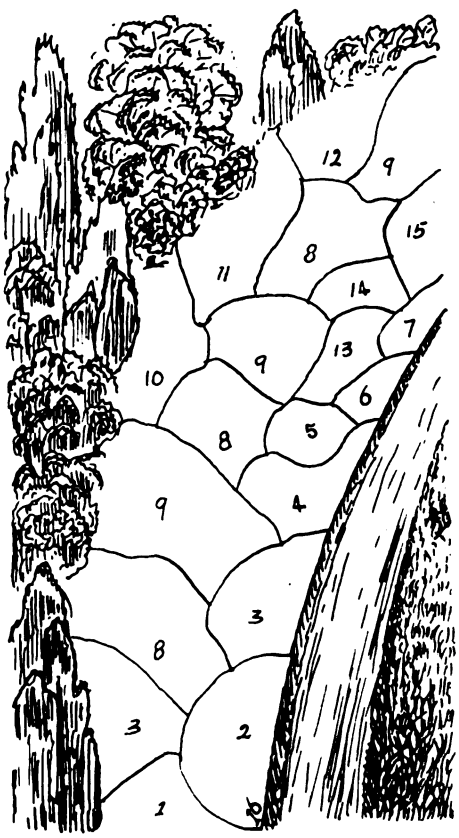
To return to actual trenching. Replace the soil taken from the trench in its original order, the top soil on the top and the second spit underneath. In replacing the latter, well mix in a liberal dressing of whatever animal manure or manures one has decided to use, at the approximate rate of one barrow-load to every 4yds. run of trench, or less if the soil is fairly rich. *It is important that the manure be well mixed and pulverised in with the soil*, and not placed in a layer. Burnt wood ashes and bone meal can also be mixed in with this layer at the same time with advantage. No animal manure should be incorporated in the top layer, but basic slag and more bone meal may be used, a good handful of each to the square yard being sufficient. If one's soil lacks lime, a good dressing of this should be scattered on the surface once every two or three years. Too frequent applications of lime tend to impoverish the ground, and this also is more or less true of chemically compounded fertilisers, generally speaking. In this connection I may add that it is wise to make organic manures the foundation when preparing one's soil for sweet peas, using the non-organic fertilisers only as stimulants at intervals during the flowering period by way of "pick-me-ups" when necessary. I hope to have the opportunity of commenting further on this point in future notes.

After the trenching operations have finished, leave the surface quite rough, and keep off it until transplanting time, when it will readily break down into a powdery condition.

C. H. A. S.

THE ODD CORNER HERBACEOUS BORDER.

THERE are many odd corners in our gardens that are not particularly beautiful at the present time, chiefly because they are not suitably planted. I have seen many corners and recesses of this kind that were suitably planted, and very charming and attractive they were, too. Now is the best time to carry out the necessary work—grubbing out old stumps, shrubs and plants, foreign matter and weeds. Then the ground should be trenched, rotted manure put in and everything made ready for the work of planting in due course. If there are large trees growing near, great success must not be looked for on account of trouble from their roots. But small shrubs may not cause serious trouble in this respect. I have made a plan which will be a guide as to the way in which such corners and recesses may be planted. If the border is deep, then some tall-growing kinds of herbaceous subjects should be planted near



the back—not too close to any existing background shrubs. If the border is narrow, then select dwarf and medium-height plants. The numbers 1, 2, 3, 4, 5 6 and 7 should contain dwarf-growing kinds and varieties; 8, 8, 8, subjects growing a little higher than the majority occupying the background clumps, namely, 9, 9, 9, 10, 11 and 12, and so on. Then may be planted, at certain intervals, several clumps of one kind of plant in various shades of one colour, as shown at Nos. 13, 14 and 15. No. 16, a suitable tile or live edging. Nurserymen will supply suitable kinds for such positions if they receive a rough plan and the space. —G. G.

GENTIANA SINO-ORNATA.

I FEEL sure that this plant would be more generally grown, seeing that it is so easily propagated, if one did "not" read the instructions usually given, that is, being a difficult plant and must have leafy or peaty soil. My experience with it might be exceptional, but it is exactly the reverse of the advice given. The first plants I had, I put in three different soils, peat, leaf-soil and pure loam. The ones in peat died after the first year, those in leaf-soil, though still living, have always looked very sickly and never produced more than three or four flowers to each plant, but the best plant has spread in three years to a solid mat 2½ft. square and has 173 flowers on it. I have just counted them to-day (November 2nd). This was planted in pure loam from the field.

More promising still are some cuttings and runners, partly rooted, which it produces freely, which I took off in March of this year, growing them on in pots till May and then planting them out into ground which had up till then been part of a lawn. This soil is a very clayey loam and was trenched sufficiently deep to cover the overturned turf, and no addition whatever. The young plants now are looking very robust and have from three to seven flowers each.

G. Farreri promises to thrive in a similar soil, but for some strange reason wireworms bite through the crowns just below the surface of the ground, although they never attack G. sino-ornata, which is growing next to it.

I saw the other day what I think must be a cross between these two varieties, and will no doubt be in great demand when it is known.—B. LEACH, *Epsom*.

TREES AND SHRUBS

PLANTING BROOMS.

BROOMS, including genistas and spartiums, are generally believed to be difficult things to transplant. This may be true of plants which are too old and woody, but even with these, say, plants up to 4ft. or 5ft. high, the greater part of them will move safely enough if the work is done in autumn or spring and one takes the precaution to cut back all the leading branches to about half way. This, as a matter of fact, is often desirable in much younger plants, for it not only renders success more certain but it encourages a more bushy growth.

We put in a good many brooms each year, and the method of planting is a simple one. The soil is never prepared in any way and the firmer it is set so much the better. A spade is the only implement used, and it is thrust straight in to its full length and worked to and fro until a slit wide enough to take the root is made. The plant is then slipped in and trodden well. We find that plants put in thus almost invariably do well and are less liable to shake loose than are those planted in soil recently dug.

So many brooms come so freely and so true from seed and grow so quickly that we prefer seedlings to any other. They are also naturally more vigorous than those raised by cuttings or grafting. But there is another objection to both the cutting and the grafted plants. Neither of them seems to take such a good grip of the soil, and the grafted ones have a bad habit of snapping off at the union as soon as the plant gets any weight of head. Some kinds cannot, of course, be propagated in any other way, but one can do a good deal for many grafted specimens by planting deep and in firm soil as I have suggested. I have never observed that brooms have any objection to being planted much deeper than one would place most shrubs.—A. T. J.

DAVIDIA VILMORINIANA.

WHEN Père Farges first sent seeds of Davidia Vilmoriniana from China in 1897 to M. Maurice de Vilmorin, only one out of a package of thirty-seven seeds germinated, and that not until two years after sowing. Later, large quantities of seeds were sent home by Wilson to Messrs. Veitch, and to

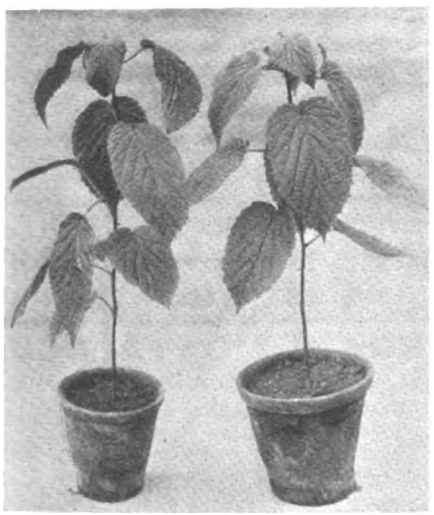
Digitized by Google

these seeds we owe the present distribution of the tree in our gardens to-day.

Wilson's seeds, like those of Farges, took a long time to germinate. It is difficult to say whether or not the acclimatisation of the tree in our gardens is responsible for the production of seeds with a quicker germinating power; but on October 29th, 1924, I gathered several seeds of Davidia Vilmoriniana in excellent condition and divided them into three groups, and sowed them the same day as follows:

(1) Seeds were cleansed of all pulp and sown in pans under glass, in gentle heat: a few of these germinated in the spring of this year.

(2) Clean seeds were sown out of doors about 2ins. deep in a nursery bed, where they remained undisturbed until March, when they were examined, and it was found that nearly all had commenced to germinate. Each seed was dug up and given a separate pot and placed in very gentle heat in a propagating pit, where they soon developed into vigorous young plants. In some instances two seedlings grew from one seed. When necessary, the plants were potted on and placed in a cold frame, where they continued



ELEVEN MONTHS' OLD SEEDLINGS OF D. VILMORINIANA.

to grow throughout the summer. The two illustrated are typical examples, and at the age of eleven months from sowing they are 18ins. high.

(3) Seeds were sown outdoors without being cleaned, and also examined in March, but none showed signs of germination.

Many readers of THE GARDEN desirous of raising plants from their own seeds may benefit by this experiment. It may be said, however, that Davidia Vilmoriniana does not appear to be fruiting so freely this year. Where possible, layering provides a good method of propagation. Cuttings, according to some authorities, will root, but, although I tried many times I failed to propagate the plant by this means until it was suggested to me that—as in the case of many "difficult" plants—cuttings should be taken from a plant growing under glass. So, finding a seedling with a double leader, I removed one shoot and inserted it as a cutting. This rooted within a fortnight, but does not grow with the same vigour as a seedling. Leray, writing in THE GARDEN of July 11th, 1925, is inclined to the view that, although three species of davidia are in cultivation, they may, for purely horticultural purposes, be grown under the name of Davidia involucrata. Generally speaking, in England we find the smooth-leaved species which Dode has named Davidia Vilmoriniana grows best, flowering and fruiting in most seasons very freely. An excellent photograph of a typical fruiting branch appeared in THE GARDEN for 1924, page 620.

Davidia involucrata was introduced by Wilson in 1906 and appears to be a scarce plant. Indeed, there is only one plant at Kew. It would be interesting to learn how many readers of THE GARDEN possess the true plant. It is distinctly felted on the under surface of the leaves and does not appear to have the same vigorous constitution as Davidia Vilmoriniana.

Dode calls a third species Davidia laeta, but this name is generally sunk under that of Davidia Vilmoriniana.—F. P. KNIGHT.

FRUIT

FORCING STRAWBERRIES.

THESE subjects are often neglected at this time of year, owing to the rush in getting chrysanthemums and other plants under glass before hard frost appears, hence it is that they need careful overhauling as soon as possible. Weeds and straggling runners should be removed and where worms have put in an appearance, the plants should be taken out of the pots with the soil complete, and examined and all worms removed. One way of searching for worms is gently to tap the soil with a flat piece of wood, and should there be any hidden in the roots, they will quickly try to escape. Where fine worm cas s are seen on the surface, lime water will prove an effective destroyer.

The plants will now need to be removed to a cold frame for the winter, but on no account should the lights be put on only when there is a deal of heavy rain. They should be tilted so that there is a good current of air circulating all the while. The frames used should be well dusted with fresh slaked lime and plenty of ashes covered over the bottom before putting in the plants. Strawberry plants in pots do well on the floor of a late peach house, providing the ventilators are kept open day and night, only closing them down when hard frost appears. The plants will just require keeping nicely moist and no stimulant should be given. Towards the end of January some heat should be put on. A temperature from 45 to 50 degrees will be ample to commence with, which should be gradually increased as the days lengthen out. Great care should be taken however not to have a high night temperature, as this is injurious to the plants.

An occasional syringing with a fine spray will be beneficial and when the flowering trusses appear some well decayed manure should be put under the pots. All trusses should be as near the glass as possible so as to get full benefit of the light. This will induce the plants to throw out roots into the manure, though the drainage hole. At this stage a little stimulant should be given them, and when all the flowers are out a rabbit's tail on the end of a stick should be passed over them when the pollen is dry, and, if a fine buoyant atmosphere is maintained the flowers will soon set. Any flowers that fail to set should be cut off, this will assist the plants to swell the fruits that have formed. As the fruits get a fair size the plants, if they are in a batch, should be tied up separately, or where there is only one row of plants a string is passed on a few sticks along the front of the row of plants.

VEGETABLES

FORCING RHUBARB.

AS soon as the leaves and leaf-stalks of rhubarb have died down and withered away, the roots may be lifted, especially if very early supplies are required; but as a rule the latter part of November or early in December is quite soon enough to begin operations. It is usual to lift a quantity of roots and leave them exposed on the ground for several days before they are placed in the forcing house. One might be careful to perform every cultural detail and yet not get satisfaction, so it should be pointed out that there are several varieties of rhubarb in cultivation, and an early variety should be selected for forcing purposes. It should also be stated that when strawy manure or other protective material is placed over and around the crowns out of doors, the naturally early varieties will push up and supply sticks for using some considerable time in advance of later kinds treated in a like manner, proving, if need be, that only varieties known to have "the quality of earliness" should be selected and grown for forcing purposes.

The roots when brought into the forcing house should be placed close together and all spaces between the crowns packed with leaf-mould or fine soil. No water need be given now, but when conditions are likely to become dry the watering pot should be freely used. Where no specially constructed forcing house exists, one need not be without supplies, as rhubarb roots can be forced quite eas ly underneath the greenhouse staging, provided darkness, moisture and a genial warmth are maintained, these being the three main requirements in the treatment of lifted roots. Succession batches should be introduced to heat at intervals of three or four weeks or as kitchen requirements demand.—D. ARMSTRONG.

PROTECTING WINTER GREENS.

TO some persons these are uninteresting plants, to others they possess a beauty all their own, and to all they are useful. The season has come when many plants may suffer injury from frosts, especially those specimens that have been grown in a rich loose soil. I recently saw a splendid batch of such plants, which will, if the winter is a mild one, do well, no doubt; but if the weather comes in severe spells, these and similar plants will suffer a great deal. Not much can be done now to remedy loose soils as the rooting medium, but earthing-up will greatly benefit all winter greens. Many years ago we experienced about eleven weeks of severe frost. I had one acre of winter greens, and just before this very severe spell of frost came soil was drawn up to the stems, burying the latter up to the basal leaves. While thousands of similar plants perished, mine remained sound: we lost about 2 per cent. The frost affects the stems where they are most succulent—just below the leaves—and if this part is buried under soil, made quite firm, the plants will survive really hard weather. Cauliflowers are best in rough frames, but exposed to the weather night and day except in frosty weather, then they will be fine sturdy specimens to plant out next spring. The due removal of yellow leaves tends to cleanliness and good health of plants, too.—GEORGE GARNER.

CROPPING KITCHEN GARDENS.

THE subject of cropping the ground in kitchen gardens embraces the preparation of the soil, the insertion of the seed or plants, their after-cultivation, the gathering of the crop and the system according to which one crop is made to follow another. As the discussion of all these points, however, would involve the repetition of what is already known to every practical gardener, this note is limited to what is called the succession of crops.

Successional cropping is that in which the ground is wholly occupied with one crop at one time, to be succeeded by another crop, also of one kind: for example, onions to be followed by winter turnips, or potatoes to be followed by kale.

Digitized by Google

Simultaneous cropping, is that in which several crops are all coming forward in the ground at the same time: for example, onions, lettuce and radishes sown broadcast, or peas, potatoes, broccoli and spinach sown in rows.

Permanent cropping is when a crop is remaining on the ground for several years, such as seakale, asparagus and strawberries, etc. The object to be attained by a system of cropping is the greatest quantity, and the best quality, with the least possible expense, and in order that these objects may be obtained there are certain principles which ought to be adopted as guides.

Crops of plants belonging to the same family or tribe should not follow each other, plants which draw their nourishment chiefly from the surface of the soil should not follow each other, but should follow alternately with those drawing their nourishment from the sub-soil. Plants which remain for several years on the soil should be succeeded by a crop of short duration. Plants the produce of which is gathered in the summer should be followed by those whose crop is gathered in the winter. These rules and others of a like kind, apply generally to the different systems of cropping.

Successional cropping.—The plants suitable for this mode of cropping are those that require during all the periods of their growth, the fullest exposure to light and air, and also remain a considerable length of time in the soil, such as potatoes, onions, carrots, etc.; if any of these crops are grown under a shade they are affected both in quantity and quality. Therefore, successional cropping must be carried out in a breadth of 20ft. or more, between rows of tall-growing crops.

Simultaneous cropping is founded on the principles that the plants for the greater part of their existence thrive best in shade, and that the plants which require light on each side should be sown or planted at some distance from each other. Such as tall growing peas are sown 10ft. apart, and between them species of cabbage, and again between these, rows of lettuces or radish, etc., the idea being to have crops on the ground in different stages of growth so that the moment the soil is released from one crop, another may be in an advanced stage and ready to take its place. For this purpose whenever a crop is removed its place ought to be at once supplied by plants for producing another crop of the proper nature to succeed it. When rows of peas have rows of broccoli between them, the moment the peas are removed, a celery trench may be prepared, and between the rows of broccoli, where lettuces were produced in their season, spinach may be sown.

Permanent cropping requires no further explanation than what has been given in the treating of the subject generally.

Of these three forms of cropping, the first is not suitable for poor soils, or where manure is limited; the second cannot be a success except when the soil is on the light side and fairly rich; the third cannot be said to be influenced by the soil in any way.—G. I.

MISCELLANEOUS

HOW TO TREAT AND USE FALLEN TREE LEAVES.

I CAN quite understand a lover of a garden envying those who have available an unlimited supply of freshly fallen tree leaves, especially those of beech, oak and birch. With the leaves, however, there are many bits of wood, mostly rotted stems and twigs, and these should be picked out carefully, as, if left in, when the leaves begin to heat, they turn mouldy and fungus results. There is wisdom in having three heaps, one of leaf-soil ready for immediate use, one of half-rotted leaves, and one of freshly gathered leaves. The heap of leaf-soil, first referred to, is so useful for sifting and mixing the finest portion with soil for sowing seeds of begonia, primula, cineraria, calceolaria, cyclamen and similar kinds in, as well as those of true annuals and biennials. The second heap referred to provides valuable half-rotted flakes, so useful to mix with soils to form potting composts, as the decay of these flakes still goes on in the pots and forms good food for the roots of the plants in them. Furthermore, in the actual heap form, if it is large enough when opened out to a depth of 2ft. or so, this leaf-soil is splendid for growing early potatoes, carrots and radishes in when a small quantity of good soil has been placed on the levelled surface. The leaves gathered this autumn will be found very useful in the formation of hot-beds and for packing, inside wire netting, around frames and pot plants to keep out frost. They also do this if placed on the roots of choice trees and shrubs, being held in position by scattering a small quantity of soil on them. In mould condition they are splendid for bulbs.—CHRISTCHURCH.

SAXIFRAGA VALDENSIS.

IT has been well said of Saxifraga valdensis, that it is frequently seen in catalogues, but rarely, indeed, in gardens or nurseries. It appears always to have been rare in these, but casting back one's memory to the days when saxifrages were comparatively few and far between, when those in cultivation were possibly more carefully tended, it was more plentiful. At least, I seem to have seen it more frequently thirty-five years ago than now. So I was greatly pleased when I saw it in a nursery the other day, tiny, close-growing, healthy plants and had a further opportunity of comparing it with S. cochlearis minor, which is frequently grown for it and not seldom sent from nurseries instead of S. valdensis. The two are wonderfully near each other in general appearance, yet to the initiated, the distinctness is quite apparent. Farrer describes the difference in the foliage in a somewhat colloquial, but definite way. He tells us that the leaf-tip of S. cochlearis minor is widened out, but flat, while that of S. valdensis is more or less puffed up and fat as well. The difference in flower is more marked, however, when the plant does flower, as the blooms of S. valdensis are borne in a fewer-flowered and denser truss on a glandular stem, while the sprays of flowers of S. cochlearis minor are on 4in. to 6in. stems, which are barely glandular and the trusses are looser and the flowers more numerous. The blooms are pure white and the effect of a plant in bloom, with the ruby-glanded stems bearing their close truss of white flowers above the densely packed blue-green foliage, is exceedingly charming. It is one of the choicest of the kabschias and should be grown tightly jammed between pieces of non-calcareous stone.—S. A.

CATALOGUES RECEIVED.

Messrs. Oliver and Hunter, Moniaive, Dumfriesshire. List of rare seeds, containing many fine primulas and a unique collection of lilies.

FOREIGN.

Messrs. Sluis and Groot's, Enkhuizen, Holland. Wholesale price lists of flower and vegetable seeds.

M. Herb of Naples sends us a catalogue of 1926 novelties of his own raising, and among them are some very fine varieties of gaillardias, Chinese asters, salvias, zinnias, and begonias, as well as such foliage plants as coleus.

Messrs. L. Férard, 20-22, Rue de la Pépinière, Paris.—Lists of bulbous plants, such as narcissi, hyacinths, tulips, eremuri, amaryllis, also a collection of irises, giving some of the best varieties, and a selection of roses, herbaceous plants and fruit trees.

WHAT IS A PLANT?

IT is often said that a little learning is a dangerous thing. Quite so. There are, however, occasions when a little learning is not so dangerous as no knowledge at all. There are degrees in this old adage, as well as in any other proverb. For instance; we know that bread is the staff of life, that it is made out of wheat, ground, mixed with yeast, salt and water, allowed to rise and then baked in an oven. We also know sundry other facts about our food: that if one swallows half a pound of raw rice it swells inside and one gets an extreme feeling of discomfort, if nothing else; that chocolate is a staver off of hunger; that meats are boiled and the essence nourishes us. How many people know how a plant assimilates its food?

Most people know how a strong wind or a scorching from a hot sun dries and tans the skin, how frost on wet skin causes chapped hands, how consistent bad weather depresses us. How many know how changes in temperature, sun, wind and frost affect a plant?

Most people know how if one stands about in wet shoes one catches a chill, how a house in a low, marshy position is often the cause of rheumatism, how excess of lime in water is supposed to form goitre. How many know in what way undrained positions or soil conditions influence a plant?

How many ordinary gardeners know anything about the whys and wherefores of a plant's existence? Very few. Some people will probably say that it is foolish to point out the necessity of knowing how and why a seed germinates and how a plant lives and dies. They say that they know if a plant is alive or dead, and that is enough; the rest is the business of the botanist.

They are wrong. If they want to get to the bottom of the enormous subject of horticulture, as all real gardeners should, an elementary knowledge of the structure of what they are growing is not only advisable, but a necessity.

A week or two ago I mentioned the necessity of disturbing the roots as little as possible when planting or transplanting a tree or shrub. From the number of letters that have been sent in, it is obvious that quite a large percentage of gardeners notice that certain plants move well and others badly, and wonder what the reason is. The letters also show how few people have the slightest idea of what is taking place below ground. There are many questions which even the greatest botanist is unable to answer; for instance, why certain plants are calcifuge and others calciphil. Most questions, however, about the reasons for the well being or otherwise of plants are answerable and many of them depend upon a knowledge of the structure of the plant.

One of the troubles attendant on the subject of botany is the technical language that has grown around the science. Perhaps this is unavoidable, but at any rate this maze of technical terms has frightened away many who would otherwise have been willing to have learnt the rudiments of botany. There is too definite a cleavage between the botanist and the horticulturist. The latter is frightened of the former, while the former often considers the latter a nuisance. If only the horticulturist would realise that botany is empirical as well as theoretical and that the botanist can help him enormously in gardening matters. The botanist could also meet him half way and try to round off and simplify his mother tongue so that it is possible for the horticulturist to understand what the scientist is driving at. There is a great gap to be bridged between the two, but the junction should not be an impossibility.

So strongly do I believe that a little knowledge of plant structure will help people to a closer understanding of their plant's requirements, that a series of articles on plant structure has been written for THE GARDEN, the first of which is given in this week's issue. These have been written in as simple a form as possible, and are, I am sure, readily understandable by all who have gardens. The first describes the plant cell; then follow descriptions of the root and its activities, the stem, the leaf, the flower, and finally the fruit. They all have their use and importance in the life of the plant, just the same as the lungs, the stomach and the skin of an animal.

Not everyone is of a sufficiently enquiring turn of mind to try to understand the basic reasons for what goes on in plant life. In any case, these articles are not written solely for his edification. They are, however, written in order that the ordinary gardener may learn something about facts which are as important to the plant as the knowledge a man has that if he does not change his wet boots he will catch a cold or a chill.

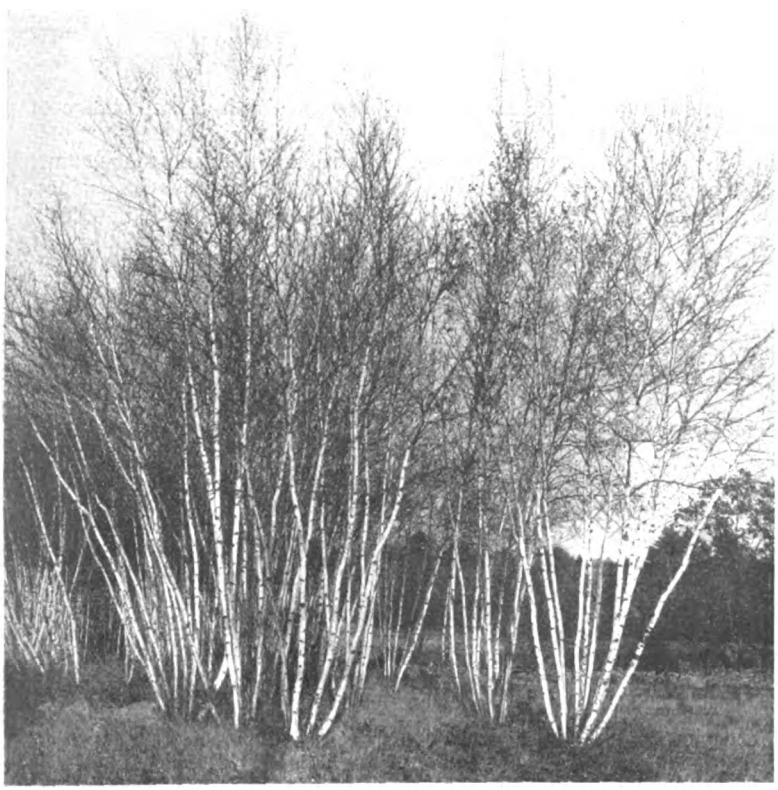
THE BIRCHES

BY E. H. WILSON.

AMONG TREES BIRCHES ARE PROBABLY UNSURPASSED FOR DECORATIVE VALUE. WITH THEIR GRACEFUL HABIT AND PICTURESQUE TRUNKS THEY ARE USEFUL BOTH AS SPECIMEN TREES AND FOR GROUP PLANTING.

BIRCHES are handsome, fast-growing trees to which greater attention ought to be paid in landscape plantings. There is much character in the bark, and the slender branches form a light and feathery crown of singular grace and charm. The genus is essentially a Northern one, ranging from the Arctic Circle to the Tropic of Cancer, with its greatest development in the Cold Temperate regions. Its southern limits are the Yunnan province of south-western China and the Himalayas. About forty species are recognised, nearly all being in cultivation in gardens like Kew and the Arnold Arboretum. Some, like Betula nana, B. glandulosa, B. fruticosa, B. humilis and B. pumila, are low, broad bushes, and B. Potaninii is prostrate, the branches often hanging down the face of cliffs. But the great majority are trees of varying size, and it is these with which this article deals.



A COLONY OF BETULA POPULIFOLIA, THE GREY BIRCH OF N. AMERICA.

The birch as a genus is singularly well equipped to perpetuate and spread itself, though it is a light-demanding tree. The male and female flowers are borne in catkins, separately but on the same individual; they are pollinated by the wind, and the fruit ripens early and disintegrates; the seeds are very light, are provided with wings, and are easily transported by the winds. Many of the white birches flourish on the poorest of gravelly soils and, being of gregarious habit, quickly form thickets and woods. All the species should be raised from seeds, and it takes but a few years to obtain trees of good size. Sow the seeds on the surface of prepared light soil, throw a thin layer of brushwood over the beds, beneath which the seeds will germinate freely and the seedlings make rapid growth. Transplant in nursery rows and, later, into final positions. Nothing in the art of raising trees is simpler than the requirements of birch. Forms of special merit, pendulous, cut-leaf, etc., should be grafted on the parent species. Though many white birches will grow in the poorest of gravelly soil, they do not object to good loam, a soil best suited to the members of the genus at large.

The majority of birches are hardy and amenable trees in the British climate. The one deciduous-leafed tree most readily recognised is surely the white birch, Lady of the Woods, of which there are about nine different species. In size and timber value the white birches are exceeded by many others; but in distinctiveness, in grace and in beauty they are certainly not surpassed. The white birches of Europe and north-western Asia (B. verrucosa and B. pubescens), of north-eastern Asia (B. japonica) and of North America (B. populifolia) inhabit the open waste places of the northern hemisphere, where they cover vast areas and often form pure forests of great extent. Moreover, they, like the aspens, are natural nurses for more valuable trees, such as larch and spruce.

Under the name of Betula alba, Linnæus confused the two white birches so abundant in Europe and northern Asia far into Siberia. These are now known as B. pubescens and B. verrucosa, the former being distinguished by its hairy and the latter by its warty branchlets. B. pubescens is the smaller and less important tree, and is partial to moist places. On mature trees the bark is dark, fissured and rugged at the base of the trunk. The best form is the var. urticifolia, a native of Sweden and characterised by its long drawn out leaf apex. B. verrucosa has silvery white bark on the trunk and main branches, polished red-brown branchlets clothed with glandular warty excrescences and pendent tips. There is no more graceful and beautiful tree than this Lady of the Woods, which, though usually about 60ft., is sometimes as much as 100ft. tall. There are several named varieties, including one (fastigiata) with erect branches and columnar habit like a small Lombardy poplar. Another, Young's weeping birch, is singularly charming with its slender hanging flagellate branches, and is the best of several weeping forms. A good variety found wild in Sweden is dalecarlica, with deeply laciniated and coarsely toothed hanging leaves and pendent branchlets.

The American homologue of the white birch is B. populifolia, the grey birch, a small tree rarely more than 30ft. tall, with a slender trunk, tumid at the base and often with a cluster of stems diverging from a common root stock; the bark is compact, firm, dull chalky white, bright orange on the inner side, with dark triangular markings at the insertion of the branches, shallowly fissured and nearly black at the base of the trunk. Very abundant from Nova Scotia southward through New England and westward, this has triangular lustrous green leaves and is a most aggressive, if short-lived, tree, springing up in quantity on abandoned farmlands and in fire-swept forest areas, growing rapidly in the poorest soils and forming a useful nurse to the seedlings of more valuable trees. Very similar, but with ovate, dull blue-green leaves and tinged with pink bark, is B. cœrulea, the blue birch. This is also a small tree native of Canada and northern New England.

Stateliest of all white birches is B. papyrifera, the canoe or paper birch of North America, with polished white bark freely separating into thin layers. It is not a very tall tree, for it seldom exceeds 70ft. in height, but the trunk is thick, from 7ft. to 10ft. in girth, and is clean of branches for three-fourths of its height. It has a small crown of comparatively few, thick branches, and it is the stout, tall, white-barked trunk that is so striking. The bark is tough, durable, impervious to water, and from time immemorial has been used by American Indians for making canoes and miscellaneous utensils and to cover their wigwams in winter. It is the conspicuous tree of the boreal forests of North America, being found across the continent from the Atlantic to the Pacific.

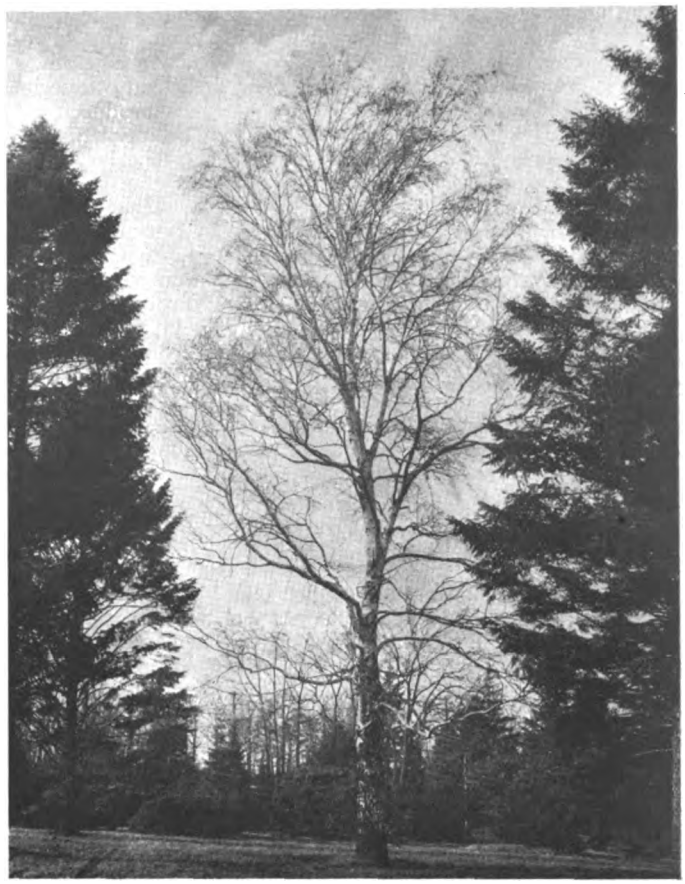
The white-bark birch of north-eastern Asia (B. japonica) is found over an immense area from the higher mountains of western China north-eastward and throughout Japan, northward

Digitized by Google

to Kamtschatka. The foliage varies a great deal, and a number of named forms are recognised, but all agree in having a pure white bark easily separating in thin layers. At its best in the forests of northern Japan, this birch approximates in size to the American canoe birch, but the best form is that named szechuanica, from the high mountains of extreme western China, which has thick, bluish green leaves and very polished red-brown branchlets and an open crown of wide-spreading branches. Trees raised from seeds (Nos. 983 and 4088) I collected near Tachien-lu have grown well in Europe and America and proved a decided acquisition.

One of the least known of all birches is the white-barked species of the north-western Himalayas (B. Jacquemontii), native of Kumaon, Kashmir and Afghanistan. It is in cultivation at Kew, and we have small plants growing in the Arnold Arboretum, but beyond the fact that the bark is white and peeling, little is known about this tree.

The most common birch in Japan and one found in great quantity throughout Korea and north-eastern Asia generally is B. Ermanii, which has a greater altitudinal range than any other Oriental species. It also grows to a larger size than any other birch of eastern Asia, with the possible exception of B. grossa, but in the alpine zone of the higher mountains of northern Japan it is reduced to a low, very broad shrub with branches prostrate on the ground. Growing in such a wide area and under such diverse climatic conditions, this species naturally exhibits much variation. The trees differ in habit, the leaves vary greatly in size and in degree of dentation, and considerably in shape also. The bark is greyish, sometimes suffused with red-brown, or it may be white; it is exfoliated in thin sheets, or the sheets may remain on the tree in shaggy masses. The fruit is always erect. Usually the trunk divides a few feet from the ground into several massive stems, and these branch to form a wide-spreading crown; but when the trees grow crowded together in rich woods, the trunk is relatively slender and very tall and the branches are thin and short. During 1914 I paid much attention to this birch in Japan, but I failed to discover any constant character by which any variety or form could be definitely distinguished in the field. Its variability notwithstanding, B. Ermanii is a well marked species. The variety (subcordata) found around Nikko, with its tall trunk clothed with peeling grey-white pink-tinted bark, is the most handsome of the many forms of this birch. In Sir George Holford's arboretum at Westonbirt there is a fine specimen of this birch. (*To be continued.*)



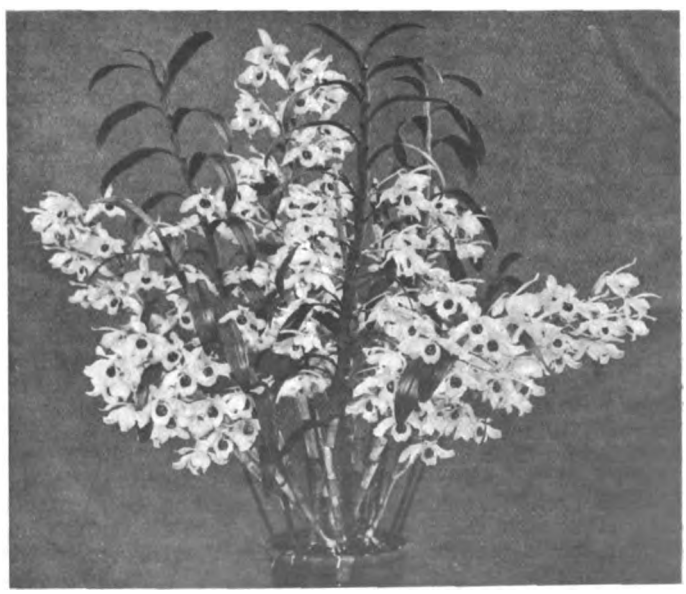
THE BEST OF THE WHITE BIRCHES, B. VERRUCOSA.

DENDROBIUMS OF THE NOBILE SECTION

BY GURNEY WILSON.

EVERY amateur cultivator of orchids has at one time or another seen Dendrobium nobile, for in past years it was imported in tens of thousands, and at a price within the reach of one and all. The comparatively small amount of attention required by this species renders it particularly useful to the amateur, while the freedom with which its flowers are produced during the early part of the year is the reason why florists select it in preference to other species of the genus. If we consider its many hybrids, it will be found that they enjoy a similar degree of popularity, in fact, it may be said that all hybrids of the nobile section respond satisfactorily to quite simple treatment, although it is true that our forefathers grew dendrobiums in very high temperatures, and thereby produced excellent specimens, recent experience has proved that equally good results can be obtained without such intense heat during the growing period in summer. Now that the old notions regarding high temperatures are passing away, dendrobiums are again becoming fashionable. Dendrobiums are especially suitable to an English climate, for they make their new growth during the best of the summer weather, and rest during the dull winter months under comparatively cool treatment. Thus it will readily be seen how adaptable they are to the conditions generally prevailing in an amateur's greenhouse.

Dendrobiums commence their annual activity early in the spring by forming new growth from the base of the bulb made in the previous year. As the season advances, so additional heat and moisture are necessary for the successful development of this young shoot, for in due time it will become an erect stem, or bulb, of one to two feet in height. The summer months are of much importance to the production of robust growth, and every opportunity should be taken of placing the plants in the most suitable atmosphere available. Many fine specimens have been grown in vineries, and in other houses having a temperature which does not usually fall below 60°. With sunshine the temperature will rise considerably, and greatly assist the production of vigorous growth; although 90°



ONE OF THE FINE VARIETIES OF DENDROBIUM NOBILE.

Digitized by Google

is often registered, it is by no means necessary that such a high figure should be maintained daily. While fully appreciating sun heat, dendrobiums must be shaded during the greater part of the day, not heavily, but just sufficiently to prevent the leaves from being scorched. For this purpose there is nothing to equal the lath-roller type of blinds, which, while allowing the sun to penetrate the house, do so in a manner that represents the partial shade produced naturally by the forest. Moisture is also of much importance, not only in the compost of fibre and moss, but in the atmosphere. Daily damping down of the house is, therefore, advisable, and on all fine mornings the plants should be lightly sprayed. Care should be taken that water does not remain in the apex of the new growth when a cold night is expected, for damage may occur if the temperature of the house falls to a low point.

About the middle of August the new growths will have completed their season's activity, and from then onwards the temperature and moisture must be gradually lessened, otherwise the plant may be induced to commence a second growth, which places it in a very unsatisfactory condition, for this second growth cannot be completed during the few remaining weeks of fine weather. Ventilation should be freely given during the autumn, and the plants gradually accustomed to full sunshine, by which means the bulbs will be properly ripened and thus be able to reward the cultivator with a fine display of bloom when the days begin to lengthen. Many a fine show of flowers has been seen when the plants have not been in a higher winter temperature than about 50°. During the winter, only sufficient water should be given to prevent the bulbs from shrivelling. The old practice of drying them so severely that they shrivel is detrimental. The true secret of success lies in the production of healthy growth being made during the summertime and judicious ripening of the same as already described. Flowers will then be produced in a quantity unsurpassed by any other orchid.

The large number of flowers produced on the bulbs reduces their vitality, and on that account it is not advisable to continue cultivating the same plant for more than a few years. Some cultivators consider five years as long enough. Probably no other orchid is more quickly and easily propagated than the dendrobium, and the method is full of interest. All that is necessary is to cut off a portion of the stem, or bulb, a few inches in length, and lay it horizontally on some damp sphagnum moss in a warm and moist atmosphere. This is best done in the springtime. After a few weeks, the buds which do not develop into flowers will produce young growths, and later on roots will make their appearance, when the little plants thus obtained should be placed in small pots and grown on in similar style to the parents.

Another method consists of cutting up one of the stems into short lengths of one or two inches and inserting them round the edge of a pot or pan. When cut into such short lengths there is only a small amount of nutriment available for supporting each new growth until such time as it forms its own root system, consequently this method is best practised when a propagating case or house is available, with a high temperature and much atmospheric moisture. It has been previously stated that in order to produce flowers the stems must be sufficiently ripened during the autumn months. But let us suppose that the owner has a particular variety of which he desires to increase the stock as rapidly as possible. All that is necessary is to refrain from ripening the stems, which is effected by keeping the plant in a shady and moist position, and the buds are then available for the production of young plants instead. The cultivator thus has the power of deciding whether the buds on the stems are to produce flowers or young growths. It is as well to point out that buds which have yielded flowers cannot be used afterwards for producing young growths.

No matter whether the plant is a year old or a specimen of large size, dendrobiums very much dislike being surrounded by an unnecessary amount of compost. It is really surprising how well they succeed when placed in pots which at first sight appear much too small. A compost consisting of about equal parts of fibre and sphagnum moss is recommended for the smaller plants, and for the largest the quantity of moss should be reduced. Good peat is now difficult to obtain, and its place is taken by osmunda fibre, polypodium fibre and Welsh fibre. During the growing season, the plants delight in abundant supplies of water, which should pass quickly through the compost. Any water-logged condition will very soon bring about disastrous results. This is one of the reasons why a mass of wet compost is so distasteful to them.

In conclusion, mention may be made of the following hybrids of D. nobile for all of them are easily cultivated and flower very freely when given reasonable care and attention. D. Ainsworthii (aureum × nobile), D. Cybele (Findlayanum × nobile), D. melanodiscus (Ainsworthii × Findlayanum), D. Euryalus (Ainsworthii × nobile), D. Lady Colman (Findlayanum × The Gem), and D. variabilis (nobile × Thwaitesiæ). All the foregoing bear flowers of varying rose and purple tints, but in D. Thwaitesiæ a hybrid can be obtained which yields flowers of a golden yellow colour, and which is acknowledged to be one of the most distinct and beautiful kinds yet raised.

A WHITE BORDER

WHETHER the white border be narrow or wide, whether it frames a pocket-handkerchief lawn with one tiny bed or a bird-bath in the middle, or a broad stretch of turf wherein a dozen or more flowering trees can find room, or even if it is not a border at all—which sounds rather Irish—but just an odd corner of the garden, it has always a delicate charm of its own and is a very pleasant possession. If, however, the white flowers are to be seen at their best, they must have a dark background, and the ideal one is a tall hedge of yew, holly or box, although shift may be made with euonymus (provided the district suits it), or even the greedy but rather unjustly abused privet. A wall of old mellowed brick is a tolerably satisfactory background, but one of stone, unless it is the red stone of the west country, is much less suitable. Immediately in front of the hedge or wall may be grown, on fir poles, Clematis montana, C. Flammula and some of the larger-flowered kinds; roses, such as White Dorothy, Pemberton's White Rambler, and the Ayrshire Félicité Perpetué, an old rose which has replaced a still older (and better) one, Seven Sisters; Lathyrus latifolius White Pearl, and Jasminum officinale; white-flowering shrubs, among them Spiræa arguta, Choisya ternata, Cistus ladaniferus, Diervilla florida alba (better known perhaps as White Weigela), and some of the Veronicas may be planted between the climbers, but unless the border is very wide it will be wiser on the whole to fill the spaces with bold groups of white foxgloves (these can be trusted to sow themselves and will keep fairly true if all pink "rogues" are pulled up), and that splendid iris, ochroleuca (unless its yellow blotches are considered to put it out of court), these being brought well forward and alternated with such taller flowering things as white tree lupins, peonies (double and single, Chinese and European) Boltonia decurrens, Chrysanthemum uliginosum and some of the taller Michaelmas daisies. That delightful little double cherry, Prunus japonica alba fl. pl. may also find a place in this part of the border or a little farther forward.

In the next section may be planted, in clumps of a dozen or more bulbs, Lilium candidum and Galtonia candicans, one to bloom in July and the other in September, combined with Phlox decussata Europa and F. A. Buchner, Anemone japonica Whirlwind, herbaceous lupins, Asters ericoides and vinimeus and flag irises, mostly of the plicata section, Campanula persicifolia and C. lactiflora alba, although in some soils the latter will grow so tall as to require a place nearer the back of the border. Clumps of the mist-like Gypsophila paniculata and the old white-striped ribbon grass, familiarly known as gardener's garters, may be introduced here and there to make a variety, for where there is no diversity of colour it is particularly necessary to get as much contrast as possible in the habit of growth and flowering of the plants used. A few bush roses of the dwarf polyantha class may be added to the list of "admissibles"; White Pet is one of the best of these for such a situation, but

Digitized by Google

I am sorry to say its name does not appear in recent catalogues. Katherine Zeimet and Snow White may replace it.

To fill the remaining space in the border there is a whole host of plants from which to choose. Particularly suitable are Achillea Ptarmica, The Pearl or Perry's White, Aquilegia Munstead Giant, Pentstemon Newbury Gem, Malva moschata alba, the dwarfer varieties of Chrysanthemum maximum, and pyrethrums double and single. These may be relieved by patches of Camassia Leichtlini, the tall spikes of which are too seldom seen in gardens, and the two anthericums, especially the starry blossomed A. Liliago—St. Bernard's lily.

How the border is edged depends chiefly on personal taste. For a permanent edging nothing is better than the old white pink, now rarely seen, alas! save in cottage gardens, whose neat, stiff-stemmed and most fragrant flowers are far superior for such a purpose, to the modern varieties with their ugly burst calyxes and limp stalks. Iberis sempervirens is another good edging plant, but it must be renewed every few years, as the old plants are apt to grow too big and if cut hard back they bloom badly. Arabis albida fl. pl. can be used as a permanent edging or young plants may be put in every autumn for spring-flowering and replaced by bedding violas in June. The annual Alyssum minimum makes a pretty and very inexpensive summer bordering, but it should not be sown *in situ* according to the general custom, but in boxes, pricked out into others and planted out singly as sturdy little plants. If the border can be slightly raised it may have what is popularly known as a "rockery edging" over the rough stones of which can be grown Viola cornuta alba, Dryas octopetala, dwarf campanulas—especially C. pusilla—those of the mossy saxifrages that have white flowers, Corydalis capnoides, Armeria maritima alba, Phlox subulata and P. divaricata, Dianthus deltoides and many other things of similar habit.

Bulbs other than those already mentioned may be introduced into our border at discretion. There are plenty of white early tulips, but very few in the May-flowering class beyond Cygnet, a fairly pure white with black anthers. Their limitations, however, are atoned for by the number of white narcissi to be found in the Leedsii section, notably Mrs. Langtry and White Lady and, of course, the old Pheasant's Eye. Immediately behind the edging small bulbs should be planted freely, including the old-fashioned "five o'clock ladies"—Ornithogalum umbellatum—white snakes'-head fritillary, the white varieties of Scilla sibirica and Muscari botryoides (slugs are very partial to the latter) and Sanguinaria canadensis, that dainty thing whose flowering season is all too short.

BOLD GROUPS OF CHRYSANTHEMUM MAXIMUM SHOULD BE INTRODUCED THROUGHOUT THE BORDER

BORDER CAMPANULAS ARE ALWAYS USEFUL.

PLANTS FOR A WHITE BORDER.

Name.	*Height.*	*Flowering Season.*
Achillea Ptarmica The Pearl	2½ft.	July-August.
Anemone japonica alba	3-4ft.	September-October.
Anthericum Liliago	2ft.	June-July.
Anthemis tinctoria alba	2-2½ft.	All Summer.
Aquilegia Munstead Giant	2ft.	June.
Aster N. B. Sam Banham	4ft.	September.
,, ,, White Climax	5ft.	September-October.
,, ,, Snowball	4ft.	September-October.
,, ericoides	3ft.	October.
,, vimineus	3-4ft.	October.
Boltonia decurrens	5ft.	September-October.
Campanula persicifolia alba	2ft.	June-July.
,, alliariæfolia	2½ft.	August.
,, lactiflora alba	4ft.	July-August.
Camassia Leichtlini	2-2½ft.	May-June.
Chrysanthemum maximum	3½-4ft.	July-August.
,, uliginosum	5ft.	September-October
Clematis montana	Climber	April-May.
,, Flammula	Climber	September.
Digitalis alba (biennial)	4-5ft.	June-July.
Galtonia candicans	3-4ft.	August-September.
Gypsophila paniculata	3ft.	July-September.
Iris ochroleuca	4-5ft.	July.
,, sibirica alba	2-2½ft.	May-June.
,, plicata section	2½-3ft.	June.
Jasminum officinale	Climber	June-July.
Lathyrus latifolius White Pearl	Climber	July-August.
Lilium candidum	4ft.	July.
Lupinus arboreus Snow Queen	4-5ft.	July.
,, polyphyllus albus	3ft.	June.
Malva moschata alba	2ft.	June-August.
Peony Single Chinese, The Bride	3-4ft.	June.
,, double Chinese, Snowball	4ft.	June.
,, Old Double White (European)	3-4ft.	May-June.
Pentstemon White Newbury Gem	2ft.	July-September.
Phlox decussata Europa	3ft.	August-September.
,, ,, F. A. Buchner	3ft.	August-September.
Pyrethrums, double and single	2-3ft.	June-July.
Sidalcea candida	3ft.	July.
Spiræa filipendula fl. pl.	2-2½ft.	June.

ANNUALS FOR THE WHITE BORDER.

Annuals may be introduced for summer flowering where there may be any vacant places, but a too lavish use of them is not advisable. The following may be tried:

Aster sinensis, white; A. s. Sutton's Giant Ray, white; Clarkia Sutton's Snowball; jacobæa, white; Lavatera alba splendens (Sutton); Nicotiana affinis; Sweet Sultan, white; ten week stocks, white.

R. E. HEAD.

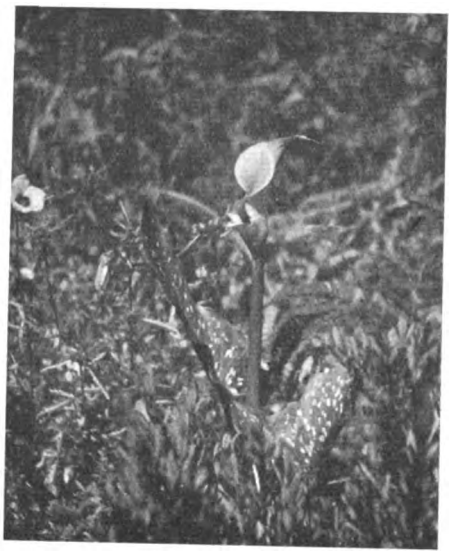
NOTES OF THE WEEK

RICHARDIA MELANOLEUCA.

THIS plant was sent to me from Natal three years ago. It was planted out in a south border and has come up every year. This year it flowered for the first time, when the accompanying photograph was taken. A second flower has also been thrown up. It would be interesting to know if any other readers of THE GARDEN have this plant flowering in their garden.—E. W. W. BLATHWAYT, *Porlock, Somerset.*



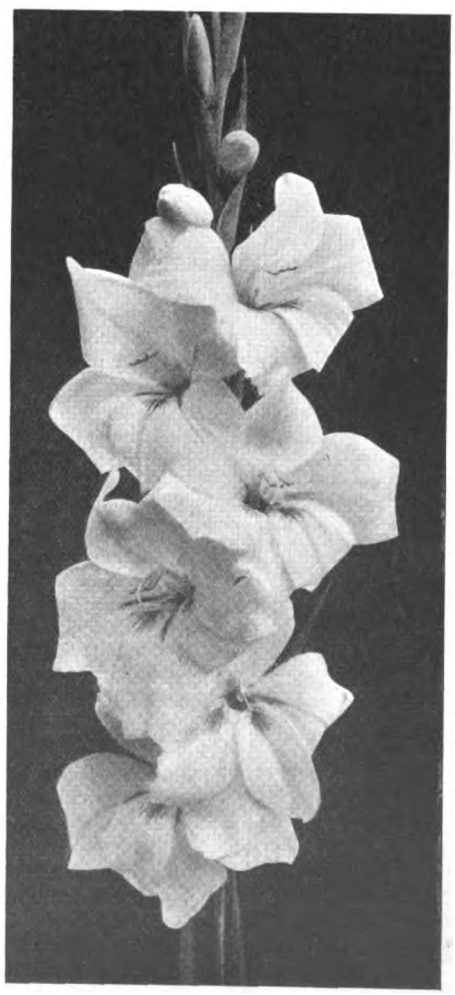
RICHARDIA MELANOLEUCA FROM NATAL.

ERODIUM HYBRIDUM.

A NOBLE plant in its way, but less appreciated because of the colour of its flowers, is the erodium called E. hybridum, which is understood to be derived from E. Manescavi and E. daucoides. It looks very well on large rockwork or in the border with its handsome, finely divided, fern-like leaves of a good green, which last during winter and decay in early spring. The flowers are of a vivid magenta borne in heads which are as large as those of a geranium. The colour is not a popular one, but the plant is really showy and striking, and when planted among or near other plants with plenty of greenery, is highly appreciated. E. hybridum is quite hardy and can be increased by division, but a large plant is much finer than a small one. For years I grew this erodium on a high part of a rock garden fully exposed, and it attracted a good deal of notice from visitors to my garden. I do not think that it seeds, as I have never seen any on my plant and do not find them offered in any trade catalogue. It should be planted in spring.—S. A.

GLADIOLI THAT HAVE PROVED THEMSELVES.

THE gladiolus year may be said to close in the month of November. The bulbs have been lifted and, with luck, should now be in their winter quarters—a dry, not too dry, airy store, secure from the reach of frost. The long winter evenings give us an opportunity to look over our notes of successes and disappointments. The new catalogues begin to descend upon us—some fully illustrated, and with such titles as "The World's Best," "Those Better Glads." "Pick the Best of the Best," and other catch phrases. Then we have the more modest titles, "The Cult of the Gladiolus," "The Modern Gladiolus," and the catalogue (which lies before me) with the simple words "Good Glads" on the outside cover, and inside I read: "My aim is not to grow the new highest-priced novelties, but such kinds as the average person wants and can afford." Turning to the first page of the catalogue proper, my eye catches the names of Alice Tiplady, Black Pansy, Catherina and Europa. Cameo attracts my attention, but I find that this is not the large-flowered variety of five years ago, but a dainty slightly ruffled prim, pink on cream ground with deeper shade on back of petals. The lower petals are yellow shading to cream white and tipped with delicate feathers of red. This one was pot grown. Chameleon, grown both in pots and in the open ground, gave satisfaction, reminding one of delicate changeable silk with soft melting shades of lilac purple, violet and orange. Elizabeth Tabor, a fine flower at any time, but with its unusual earliness (always one of the very first with the writer), it is doubly appreciated. Next, Giant Nymph, gigantic in both growth and flowers, and we once more picture the early blooms of light rose pink with creamy yellow throat. Golden Measure, Jack London and Jenny Lind are, perhaps, too well known to need further description; but Jasper, with its distinct feather of velvety amaranth purple spread over light zones of clear yellow, and Lena Graetz, a good white, are noted as two to be put on the list for next year. Both bloomed well in pots and the open ground. Under the letter "M" we are once more brought face to face with those popular favourites, Mary Pickford, Mona Lisa, Mrs. F. Peters, Mrs. H. E. Bothin and Muriel. Odin calls to us from that outstanding patch of colour last summer that he too must not be overlooked. Elora should have been mentioned as growing in public favour. It is a Burbank production, the colour is creamy white with cream spot in throat on three lower petals which are overlaid with featherings of American Beauty pink.



A HANDSOME SPIKE OF GLADIOLUS ELORA

Purple Glory, Romance and Rose Ash come next in view, with the new prim. Revue, a yellow, shaded to delicate pink at tips of petals, insisting not to be overlooked. This last was planted on June 8th and bloomed September 10th, and is sure to attract attention when better known.

Scarlet Wonder, with its mammoth pure deep scarlet flowers, claims a space in the mixed border; while Sheila and Sweet Lavender remind us that they are among the first to bloom and furnish us with bowls of delight.

Indeed, they are all "Good Glads."—G. C.

ANTHOLYZA PANICULATA.

OF late autumn flowering hardy bulbs we have comparatively few of greater effect than the antholyzas from South Africa, bold-looking plants in both leaf and flower. Of the few in cultivation, Antholyza paniculata is the best, as it is hardier than the others, is as fine in the garden, and is not difficult to procure from ordinary trade sources in this country. Like most other flowers, it varies in height, according to the nature of the soil, and is generally about 3ft. high in medium loam. It is really handsome, with long, erect, bold, plaited leaves and masses of scarlet and yellow flowers, much after the style of the montbretias, to which it is closely allied. It is more effective in the garden than they, however. If planted, as soon as received, in loamy soil—well drained and, if the compost is poor, with some thoroughly decayed animal manure or some bonemeal added—at a depth of about four to six inches, and covered for the first winter with some dry litter or a mound of ashes, it will establish itself and increase from year to year until it forms a bold clump of much beauty.

The variety A. p. major is taller and bolder, but it is rather later of flowering, and in cold localities is often caught by frosts before it can bloom. Its flowers, also, are of poorer colour, and its main value for all but mild places lies in its noble leaves. Some cut down the old foliage every autumn and cover the surface of the soil with litter, but the old leaves afford a valuable protection if allowed to remain until the new leaves begin to appear, when they can be removed.—S. ARNOTT.

A NEW USE FOR ELYMUS ARENARIUS.

"NO, you don't," says Elymus arenarius to the encroaching sea. "No, you don't," it says to inquisitive see-ers in a flat wind-swept garden close to the shore at Blundellsands, near Liverpool.

This is how it came about. A drive of some 40yds. to 50yds. in length leads from the gate to the front door. All along one side of this drive are the tennis courts. The owner's problem was, what to do to secure their privacy? Casual visitors are all very well in their way, but one does not want them to see all that is going on. A wonderful inspiration came to him. Was it a leaf from the sand-hill's book? or was it a sort of sub-conscious application of the Doctrine of Signatures? What could restrain the sea surely could also restrain see-ers!

Anyhow, the idea fructified, and a big bank of sand was made all along one side of the drive. It was ever so wide at the bottom and about 8ft. or 9ft. high, with

Digitized by Google

an equal slope on either side, towards the drive and the courts. This was planted all over with Elymus arenarius. I saw it in 1922 and again this year. The result is fine. It looks well and it does its work well. The gardener tells me that practically the only attention it gets is that the whole of the grass is cut down to within about 6ins. from the ground at the end of December or in early January every year.

I can imagine nothing that would have looked so well, or have been so permanent for the purpose for which it was needed, as this wholly artificial grass-covered bank.

The idea may be useful to some of our readers. I do not know if this grass will flourish away from the sea. If it does, well and good. If it does not, would Elymus glaucus do for a substitute, or would it be too tall and rampant?

Of course, one cannot dump such a bank anywhere. Environment *must* be considered. —JOSEPH JACOB.

EUONYMUS BUNGEANUS.

I SHOULD like to bring to notice the garden value of Euonymus Bungeanus, a Chinese member of this widespread genus, which has been in cultivation in this country since 1883, if not earlier, and is worthy of much more attention than is paid it at present. It was named by Maximowicz in the nineteenth century after Dr. Bunge, the well known botanist, but it is believed to have been first discovered by Cunningham, a Scotchman in the East India Service, about the year 1705, and was certainly found by some members of Lord Macartney's mission to China in 1793. Apart from any historical interest, its grace and creamy colour in the autumn give it a singular charm. It is certainly not so showy as some forms of E. alatus and E. europæus with their violent variations of colour, but a satisfying, if gentle, cream makes a pleasant contrast to the more brilliant shades. This species grows into a large shrub or small tree, and is more graceful in form and outline than many of the commoner species. The leaves are long and wedge-shaped at the base, and taper to a slender point. At this time of year they hang in a most graceful fashion perpendicularly from the branches, and the delicate shades taken by the leaves from creamy white to a pale fawn catch every glint of light. It rarely fruits in this country but the beauty of its foliage more than makes up for lack of fruit. It is perfectly hardy and will grow in any good loam.—E. C.

A GOOD CLUMP OF CHIONODOXA GIGANTEA.

CHIONODOXA GIGANTEA.

IN the notes in THE GARDEN on bulbs for present planting, I saw no mention of Chionodoxa gigantea alba. I imagine that this bulb must be rare, as I find no mention of it in the catalogues which I have consulted.

To my mind, its blooms are far more beautiful than those of C. Luciliæ alba. A few years ago I bought one bulb, and now I have a good patch of it, of which I send a photograph. When in bloom I consider it the most beautiful flower in the rock garden. — NORMAN RUSHWORTH, *Walton-on-Thames*.

THE UNEXPECTED IN GARDENING.

IT is the gardener's privilege always to be prepared for the unexpected. Nine-tenths of his work is more or less experimental, and even he who exercises his craft in a comparatively small way is constantly being confronted with something new—something, it may be, that is a direct contradiction to general experience. Take the following instance. In the spring several old clumps of Dierama pulcherrimum in a neighbour's garden were lifted, the object being to divide and replant them. Wise people wagged their heads. The project would certainly not succeed, for these plants when fully grown are by common consent notoriously bad movers. To make matters worse, the clumps were thrown loosely into a box and there they lay for several weeks, fully exposed to the weather. However, the gardener, finding them still alive, eventually took pity on them. He broke them up and planted them. They made an immediate response, and the last time I saw them, about a month ago, they were carrying promising sheaves of green blades.

Genista monspessulanus I have grown for many years and, though I was under the impression that I knew all there was to know about the culture of this shrub in a general way, it held a surprise up its sleeve. It happened that a group of considerable size had become so leggy that preparations were made for replanting with seedling stock, as is usual with most things of this sort. The bushes (8ft. high) were therefore sawn off an inch or so above the soil, the result of this being that every one of the stumps put up such a strong array of shoots that these will soon refurnish the patch and promise to make better bushes than the seedlings. Many brooms will break from the old base after cutting down, but only in a feeble, half-hearted sort of way. The stumps alluded to have shot up with the vigour of gorse.

Here is another incident which some may be able to explain. The plants and shrubs of a narrow westerly border are so menaced by a high tree-clad bank behind them that all the taller kinds naturally lean out to the light. But there is one notable exception. Some plants of Genista fragrans put into this border were given the additional shelter of a large laurustinus on the wall above them. But, in spite of the fact that the latter has grown so much that it now forms a dense canopy over the genistas, these shrubs are as erect as ever they were. Instead of leaning away from the shade, as all the other things are doing, they have actually grown right into it, thrusting their leaders into the branches of the evergreen above.

The relative hardiness of plants is a subject upon which few gardeners can afford to be dogmatic, for, within reasonable limits, there are subjects which, if they fail in one climate, may do quite well in another part of the county. Fremontia californica, for example, has withstood, without any injury, frosts which have been severe enough to kill subjects usually considered much hardier, the exposure being equal in each case. Yet many who might grow that singularly beautiful shrub are deterred from trying to on account of the warnings uttered as to its tenderness. Then there is Raoulia australis, which has laughed at 26 degrees of frost and carried on cheerfully under wintry conditions that have turned the prostrate thymes brown.—N. WALES.

A BEAUTIFUL EUONYMUS, E. BUNGEANUS

CARPETING THE SPRING BULB BEDS

WE particularly dislike those mounds of bare soil—beds in which bulbs are planted—that inevitably present the appearance of graves—graves of departed summer. Besides, they are so unnecessary. Ten minutes perusal of any good plant list will convince you of this, for Nature has been lavish in her provision of delightful plants wherewith to "carpet" the bare ground during the winter days, plants that immeasurably enhance the beauty and charm of the spring garden. A bed of Darwin tulips may be good enough to stand alone, but its attraction is immensely increased by underplanting with alpine phloxes or forget-me-nots that flower at the same time. Here are almost infinite possibilities in colour blending and colour contrast; while, by pressing the aubrietias, too, into the service, the scope is widened to embrace a far broader range of tulip brilliance.

Imagine, for instance, the effect of a bed of Tulip Bleu Aimable carpeted by Aubrietia purpurea. Or Tulip Farncombe Sanders, in almost geranium scarlet, over a groundwork of the snowy white Phlox subulata Little Dot. Tulip Clara Butt is one of the cheaper varieties that consort admirably with Phlox rosea grandiflora. There is a peculiar aptness in the association of Tulip Euterpe in soft mauve with its electric blue centre and Phlox subulata Seraph, the white flowers of which also display a blue centre.

There is a curious old-world primness about the Dutch hyacinth that almost demands the company of the equally old-fashioned double daisy that begins to flower so early and lasts right up to the day when the beds are cleared for their summer occupants. In this connection, do not overlook the merits of the varieties Dresden China and Hen and Chickens. The former is simply ideal for use with small bulbs in small beds, and gives a complete surfacing of miniature quilled flowers in soft pink, while the latter has all the charm of the country cottage garden, where, by the way, it is most often seen. The flowers in this case, too, are pink and very double, each one being surrounded by "auxiliaries" in the form of smaller blooms clustering round the central one, like chickens round their mother. Strong red, crimson and scarlet flowers may be thrown into most striking prominence by underplanting with Cerastium tomentosum, which provides a neutral grey silver carpet, the effect of which in a big bed is most attractive.

The fresh green mossiness of the saxifrages serves us nobly in a variety of ways and, with the splendid forms now in commerce, not only provides a vivid green carpet all through the winter, but so profuse is the flowering that this is entirely buried beneath a welter of red or white flowers when the bulbs are at the zenith of their perfection. Where tall-growing May-flowering tulips are a feature, do not overlook the marvellous possibilities of the polyanthus, especially where these are segregated into separate colours—white, yellow, gold and red. Here one may select, combine and associate to almost any extent and, by cunning planting, almost complete satisfaction may be ensured. As a simple groundwork, that sturdy old favourite Mrs. Sinkins pink is difficult to excel and, if you have never experimented thus, just try planting beneath a vivid orange tulip, such as Walter T. Ware, a variety that deserves special commendation for its lasting qualities.

Here is a little trick that enormously enhances the apparent silveriness of the pink's foliage and throws up the brilliance of the orange tulip. Plant a small proportion of the "black" tulip—The Sultan—among the orange ones. This must not be overdone or the effect is spotty and crude, but a few form that slight "leaven" that makes all the difference to the mass. With a large space to fill, no cheaper way can be found than a sparse planting—say 15ins. apart—of cottage or Darwin tulips, filling the groundwork with Arabis albida fl. pl.

So far we have only considered association of plants of a spreading nature with bulbs, but particularly attractive beds may be planned by interplanting bulbs with bulbs. Thus narcissi may be grounded with muscari, the intense gentian blue of the latter serving as a splendid foil to the delicate colouring of the best forms of narcissi. Anemones, too, are invaluable and very economical, because with these we obtain beautiful spreading foliage as well as flowers. Justifiably popular for its wealth of double golden blooms, so familiar as Gold Dust, Alyssum saxatile fl. pl. gives us glaucous grey foliage all through the winter, which is completely hidden under gold in April and May, so that it is suited for use with a wide variety of bulbs.

A very beautiful woodland bed, suitable for a half shady position, can be achieved by the use of two simple and familiar flowers. Use the common English bluebell—Scilla nutans—at 9ins. apart all over the bed and, between each bulb plant one root of Anemone nemorosa—the familiar wild wood anemone. If you want to translate the same idea into garden varieties, choose Scilla campanulata alba with its spikes of pure white open-belled flowers and substitute Anemone apennina as a groundwork. The latter covers the earth with beautiful green leaves and masses of starry bright blue flowers.

H. W. CANNING-WRIGHT.

A PLEASANT ASSOCIATION OF TALL DARWIN TULIPS AND FORGET-ME-NOTS.

CORRESPONDENCE

MYRICA ASPLENIFOLIA AND LONICERA CANADENSIS.

SIR,—I was interested at seeing a very good snapshot of a small plant of Myrica asplenifolia illustrating "G. C. T.'s" interesting note on shrubs in Argyllshire, and also in what was said regarding its presence as evidence of the mildness of the west coast of Scotland. Out here (Canada), it is an absolute weed, quite hardy, and runs for miles along the driest railway banks, where, in company with Lonicera canadensis it forms a charming effect, especially in early autumn when the latter has turned its rusty bronze hue.

This is again one of those proofs that snow is the most wonderful blanket, as well as fertiliser, for native plants. Cassell's dictionary gave two of the Canadian orchids—Calopogon pulchellum—as being "nearly hardy, but . . . it is better to give it greenhouse treatment," whereas I know of it literally covering a rotted tree stem that lies out in the water of a lake in the Gatineau country to the north of Ottawa, and Pogonia ophioglossoides, as needing a temperature of 50 degrees, though that is another plant which thrives in the wet Canadian meadows and swamps! It is most curious to see how hardy some of these so-called tenderlings can be in their native land. And hardy the poor things need to be, with a temperature going down to 40 degrees below zero at times.—EVELYN BYNG OF VIMY.

GARDEN RUBBISH.

SIR,—It came as no surprise to find my views regarding the dangers that lurk in garden rubbish are challenged. Your correspondent T. E. Tomalin considers I have "greatly exaggerated the dangers likely to arise therefrom." Let me assure him that nothing will please me better than to discover that he is right, and myself wrong: for, after all, it is a matter of very small importance that I should be bowled over as compared with

Digitized by Google

the gravity of the danger, if it is as great as I believe it to be.

My anxiety is not to prove that everything I write is infallibly correct, but, by the expression of my views and throwing them open to discussion and criticism, I venture to hope we may make some progress toward arrival at the truth.

Permit me further to explain conclusions at which I have arrived.

We have been taught by scientists that many of our most destructive fungoid diseases ripen their pustules of spores on the decaying foliage and growth which the fungus helped to destroy, and that these pustules frequently pass their dormant period either on the rotting vegetable matter or in the soil beneath, eventually distributing their spores for a renewed attack upon their favourite hosts. Eggs of aphides and various other insect pests are likewise deposited on twigs, leaves and stems of plants and weeds, and many pupæ of leaf-miners and other foes hibernate in the garbage of the plants they have attacked. Every plant pathologist who lectures or writes constantly reiterates the importance of burning the diseased plants or parts of plants which have to be grubbed up or pruned away, and in a good many cases that is admitted to be the only known method of stamping out the particular scourge under consideration.

Despite all this, it is all too commonly the case that mildewed foliage and prunings, maggot-infested celery tops and heaps of other infested rubbish are either dug directly into the soil or are conveyed to the rubbish heap to make humus. Potato haulm, full of disease, and even rotten tubers are carelessly left to perpetuate their enemies; and dropped fruit, as well as small prunings, occupy some place in the garden long after they should be destroyed; and vast quantities of weeds are left to rot which are smothered in pests of varied description. Such methods cannot be hygienic.

Your correspondent mentions that he has reduced the pests that worried his plants by improved methods of control; it follows, naturally, that his garden refuse is the cleaner, and therefore less dangerous, and I have not said a word against conversion of clean refuse into humus. My opinion, however, is that much of the complaint regarding mediocre success of spraying, etc., is traceable to the carelessness that is prevalent in dealing with diseased rubbish. The value of humus has been so persistently emphasised that the opinion has become widespread that the thing that matters most is to make all the humus possible, using anything and everything for the purpose. The truth is, a majority of soils possess humus enough and to spare, and many garden soils are seriously overcharged with humus. At any rate, clean humus must be better than diseased.

In so far as leaf-mould is concerned, I readily confess to considering it a grossly overrated commodity, and I know I am not alone in attributing many troubles of pot-grown plants and seedlings to leaf-mould. Some of the largest and most successful commercial growers long since dispensed with leaf-mould for many of their cultures, and the biggest growers of perpetual-flowering carnations forbid the use of leaf-mould in their potting composts.—A. J. MACSELF.

LONICERAS.

SIR,—In Mr. Hadden's splendid article in THE GARDEN for November 14th, page 639, I was sorry to see Lonicera involucrata omitted. The flowers are yellow, but its charm is in its fruiting stage, when the large leaf-like bracts turn the most lovely deep red in the autumn and surround berries of reddish black colour, a vivid contrast to its deep luxuriant foliage. It is a shrub which grows from 5ft. to 6ft. high, and is a native of North America.

Most of the other varieties Mr. Hadden mentions grow in these gardens, but we failed completely with Lonicera Hildebrandtii. Among others growing here are L. utahensis and L. canadensis, the latter in bloom at the present time.—R. MOORE, *Thorpe Hall.*

PLANTS IN EAST ANGLIA.

SIR,—Lady Byng of Vimy will find, I think, that the east coast of England generally suits shrubs and flowers that require sunshine and a dry air, while the west coast suits the shrubs and flowers that love moisture and a more even temperature. If on the east coast you can find an ideally sheltered spot (I know of more than one), the increased power of the sun with its actinic rays that are so soon dulled by damp or smoke compensates for occasional cold spells. It may be quite local I grant, but it can be found, so that while tree ferns cannot adapt themselves to eastern conditions, there are many Chinese and Eastern shrubs that will flower much more freely on the east coast than on the west coast, which is warmer in shade but wanting in sun. There are always puzzles why a plant will thrive in one garden and die in the next, and it is that that adds interest to the keen plant lover. For instance, I saw last summer in the grounds of Mulgrave Castle a very fine Araucaria imbricata planted the same day as that at Kew, but infinitely better grown and healthy. It was one of those scorching hot days of last July, and resin was issuing from every pore of its bark. Horrified at the sight, which seemed to presage death, I asked the gardener about it. "Oh, sir," he said, "it always does this in hot weather, but I never saw it so bad before!" That grand araucaria at Dropmore died from this cause I knew, so judge of my interest when I met an acquaintance who had just been to Patagonia where these araucarias are native. I was told that in summer in that bleak land the thermometer never rises over 60° *in the shade* or falls below 40° in winter, so constant and strong are the sea winds. So in this case it is a hot day that kills the tree, while in many cases it is the want of a good hot sun that makes it drag on a miserable existence. At Scarborough in Yorkshire many very interesting facts may be learnt in the well planned public gardens there, and I recommend them to gardeners.—E. H. WOODALL.

PERENNIAL LOBELIAS.

SIR,—Under the above heading on page 602, Captain H. G. Hawker expresses his satisfaction with the various kinds he grows, all, I believe, raised by us. Particularly was I pleased to see he justly values the variety Mrs. Humbert. This, in normal circumstances, is a very beautiful plant, dwarf and bushy, covered with pretty pink flowers—which, if individually small, are so profuse as to make the plants literally pink bushes—as many as fifty branchlets radiating from one strong crown being frequently seen.

Captain Hawker deplores the loss of richly coloured foliage as in the more tender species. *A propos*, I should like to say that the origin of this race is a fusion of the hardier North American species, all having green foliage. My father, Mr. B. Ladhams, some thirty years ago conceived the idea of a perfectly hardy race, but could find no large-flowering or bronze-foliaged species which answered his requirements. He therefore set himself to evolve at least the former. It was a long business, as in all the first crosses—indeed, for many generations—the resultant seedlings gave nothing but dull washy colours. However, the best of these were selected again and again until a break occurred, giving really promising colours. This is the jumping off place of the present hardy and brilliant coloured varieties which I am handling under my father's watchful eye now.

I may add that in reference to the Rev. Jacob's appreciation of these plants in the issue of October 3rd, Mr. B. Ladhams has had recourse to no outside assistance in this work of crossing and selection.

Returning to the point about coloured foliage, it so happens that this year's batch of selected seedlings contains two or three quite richly coloured, but retaining the characteristic habit of the original crosses. The difference in the form of the flowers in this series and those of cardinalis varieties is quite distinctly marked, and one accustomed to handle both can at a glance pick out the hardy race from the tender one. A sport from Shirley Beauty has now developed quite a deep beetroot-coloured foliage, so we seem to be on the way to rich foliage as well as hardiness—the all-important feature to retain. Of the purples, Delight and Purple King are magnificent pieces of colour when well grown.

A propos of Captain Hawker's remarks as to division, we always get the best results from spring-divided crowns planted fairly thickly (say 9ins. apart) in rich damp soil.—ERNEST A. LADHAMS.

BOX EDGING.

SIR,—I fully sympathise with all "Claremont" has to say (page 642), regarding the labour involved in the upkeep of box edging and the ruinous effect it has upon the soil intended for any plants or shrubs within reach of its hungry mat of roots. The trouble of digging up and replanting, this very soon after the edging has begun to look fine and shapely, as well as the clipping entailed, are formidable tasks when labour has to be considered. But there are other features of box edging which are, to my mind, not less objectionable. Snails love box edging and every variety of slug seems to make its shelter their headquarters. Then there is the odour of box. This may not be unpleasant in itself. Indeed, it is rather refreshing, though suggestive of the venom which lurks in the green blood of all the spurges. But on any warm summer day the fragrance of any flowers in the immediate neighbourhood of box is overwhelmed by the latter's characteristic smell. I have been in many a good rose garden when at the height of their summer beauty, only to find the perfume of the roses entirely subjugated by that of the box which surrounded each of the beds. Box edging may be practically an essential in the making of certain styles of old-world gardens, which is good and well. But where it is not an essential it seems to me that there is very little that can be said in its favour.—A. T. J.

HELENIUMS.

SIR,—In addition to the several good varieties given by the correspondent in Notes of the Week on page 657, there is at least one other sort most worthy of mention, namely, Helenium pumilum. We grow this variety somewhat largely here, using it in summer bedding colour arrangements with other shades of yellow and apricot tones. I do not hesitate to designate it one of the best, if not *the* best of the sneezeworts. In height it averages 18ins., not more. When in flower H. pumilum is one of the most showy plants in the garden and one of the freest blooming, too. The colour is a clear yellow self, perhaps one might call the shade a rich lemon. Continuous flowering is much aided by the removal of passing flowers and, should the season prove very dry, a timely watering or two may be necessary to this end—on light soils, anyway. The late summer rains of the past season suited our subject perfectly, as could be judged by the bright sight of blooms in early October.—C. T., *Ampthill Park.*

PLANT RAISING AND ROOT DISTURBANCE.

SIR,—The Editorial comment in THE GARDEN (November 7th, page 621), on this important question is worthy of the best thought. Every young man or youth who has chosen as his life's vocation the craftsmanship of gardening should take every opportunity of making himself as fully acquainted with every source of information he can get on such a vital part of a plant's anatomy as the roots. To know the A B C of root-action in all its ramifications, from the confined pot space of any given plant to the larger expanse of all shrubs and trees, is to be in possession of an invaluable asset of horticultural knowledge. In the whole realm of the science of horticulture, there is no aspect of culture which has so much to do with either success or failure as a right or wrong conception of what part the roots of all plants have to do with one or the other. There can be no healthy functioning of stem, leaf, flower or fruit if there is inefficient root action. Therefore, the ventilation of such a subject gives most valuable assistance to every craftsman in the art of culture. As a past teacher of Council gardening classes, one was confronted with persistent questionings, one of which was how best so to raise plants that, when ready to plant into their growing quarters, they would go ahead without a check through disturbance. Many methods of doing this were taught, but none was so satisfactory as the following. I made a box 18ins. by 12ins. by 3ins. deep, then cut a turf just sufficient in size to drop in grass side down, and a little thicker than the depth, so as to allow for paring down to the side level of the box. This done, I cut the turf into six lengths 2ins. wide and then crosswise nine times, making a clean cut through, so that each of the fifty-four 2in. squares would separately lift out. This practical demonstration was simple in preparation, its success in doing what it was suggested it would do was eagerly awaited. A small circular hole in the centre of each section was loosened up and prepared for either sowing a seed or planting in a seedling. The process went on until planting-out time came, when in each square there were plants of various sorts well rooted and established, which were easily taken out, transferred with soil, roots and plant complete, one special essential being seen to, that each square was moist right through, so that no suffering from this point of view should take place. The whole scheme became so successful that it is in practice, not only by my old students but by myself, as one of the most sure systems of culture of small plants. It is also the most economic in cost, labour, space and, not least, in the gain of time saved by not disturbing the roots.—V. H. LUCAS, *Hurworth-on-Tees*.

BOTANY FOR THE BEGINNER—I

THE PLANT CELL, THE BEGINNING OF ALL PLANT LIFE.

IN this and the following articles, I will endeavour to present to the reader a few of the essential and fundamental facts concerning botanical science, or the study of plant life, in simple and non-technical language. The beginner is, in nine cases out of ten, frightened by the formidable tomes dealing with the subject, and generally decides to give them a miss and devote himself to some other study which can be approached more easily.

Let me, therefore, commence at the beginning — the source, the fountain head as it were, whence all plants, probably all animals, and hence all life, have sprung. It is now generally accepted that all life originated in the sea through the interaction of the so-called ions in the seawater. This vast expanse of ocean teems with millions of living organisms, from the largest fish down to the tiniest of crustacea and flagellates, diatoms and one-celled plants—known as the unicellular algæ. These latter are clearly seen in sluggish streams, and comprise the green scum which floats or lies on their surface. Here we have the simplest form of life that is known to-day. Within one tiny oval or spherical sac, bounded by a thin and transparent elastic wall, all the constructive and dynamic processes which go to produce what we choose to call life take place. Even man, with his laboratories and his elaborate technique and skill, along with his intimate knowledge and close grasp of nature, cannot do what this tiny green speck does. It is the pinnacle to which all scientists would like to attain, and at present it seems improbable that they will ever reach it. Scientists know much of what is to be known about the green cell, but they lack the knowledge of that something which, for want of a better term, may be called the driving force—the engine which produces the necessary interaction of the chemical constituents of the cell and induces organic activity. What does this green cell do? It constructs or synthetises the food material so necessary for the vital activity of the organism, resulting in the case of the plant in growth, and in that of the animal in growth and movement. In much the same way the engine converts the fuel with which it is supplied into the power that is harnessed to drive our machines. Hence this little green cell may be looked upon as one of the greatest of cosmic facts. It builds, from simple inorganic elements, complex organic compounds; and herein lies the fundamental distinction between animals and plants. The animal can only make use of organic material which is already manufactured as such. Unlike the plant, it cannot form from such comparatively simple substances as carbon dioxide (of which there are 3 parts in 10,000 of air) and water the necessary organic matter required for all life's processes. Thus the simple unicell may be looked upon as a factory—a manufacturing centre—wherein these synthetic processes are carried on. The green cell in fact, whether acting as an isolated unit or leading a corporate life, is the chief agent in the production of organic food on the earth's surface.

It has already been mentioned that this cell, or structural unit, resembles a closed vesicle or sac bounded by a limiting membrane or wall which is transparent and capable of stretching and contracting at will. It varies in shape from spherical to oval and from square to rectangular, according to its position and the function that it has to fulfil in the plant body. When the cell is alive and fulfilling its normal functions, the wall will be tense and taut—*i.e.*, a high pressure is maintained in the cell cavity—in the same way as the bladder of a football is in a state of tension when blown up. Within the cell is contained the cell sap, a thin fluid composed of water with dissolved substances in dilute solution. It is these substances, owing to their strong attraction for water (termed "osmotic attraction"), that cause the tension within the cell, resulting in the stretching of the wall and the formation of spaces called vacuoles filled with this watery sap. These ultimately all join together to form one central vacuole. This cavity is limited by the cell wall and is controlled by a living layer or film of plasm which is just within the cell wall, forming an internal lining to it—what the bladder is to the outside cover of a football, to use our previous illustration. In this plasm—the cytoplasm or living substance—is embedded a body of the greatest importance in the functional duties of the cell. It is the nucleus which governs the growth and reproduction of the cell. This body, composed of denser plasm, appears in the form of a fine network of strands irregularly thickened. The whole structure is encased in a thin membrane and a sap is contained within. From this network at the time of cell division there arise the chromosomes by the breaking up of the threads or strands into minute pieces. It is now generally accepted that the chromosomes are the bearers of hereditary characters, and are of outstanding importance in questions of crossing, heredity, variation and evolution. Since these parts are all colourless, the grains which carry the green colouring matter known as chlorophyll stand out on microscopic examination.

Just a word in passing regarding chlorophyll. It is made up of four pigments, and these are present in what is termed a colloidal solution (a solution like starch and water). Large numbers of these chloroplasts (colour bearers) are to be found in a single cell of this description embedded in the general plasm. Those which lie in the peripheral plasm do not remain fixed in position but move according to the degrees of light intensity; and here we have the explanation of why, for example, a leaf growing in the shade is dark green, while out in bright sunlight it is of a lighter shade.

One question which will naturally be asked by the beginner is why these bodies are green. The answer is because of their relation to light. Everyone knows that light (the sun's rays) can be analysed into a spectrum of colours, as is clearly seen in a rainbow, and if a beam of light be projected through a solution of chlorophyll the resultant spectrum after traversing the solution will show dark absorption bands. These occur mainly in the red and violet rays, with a slight one in the yellow, which leads us to suppose rightly that part of these rays is absorbed and held by the chloroplasts, the green colour

Digitized by Google

being allowed to pass on. The light received in this way, which must be of a sufficient illumination, constitutes a supply of energy which is stored up till required, and is the real active force in the formation of the necessary combustible material. We have already seen that each cell must have a full supply of water in order to function normally, with, in addition, a plentiful supply of atmospheric air which contains the carbon dioxide gas. In a later article we shall see how those two fundamental substances are supplied to the cell when we discuss the green leaf, and that how with light, a certain minimum of temperature, air and water, the vital activity of the cell, and hence of the plant, which results in growth and all its attendant physiological processes, is carried on.

It may suffice here to state that, through the interaction of these raw materials and the stimulus of light-energy, certain creative changes take place which result first in the formation of sugars, which are later converted into a less insoluble form which we know as starch. This is stored and forms a source of potential energy and food supply. Thus we have arrived at the end point, the formation of starch—a carbohydrate—from carbon dioxide and water, aided by a certain temperature and the energy of the sun's rays.

One cannot fail to realise the extraordinary importance of the individual green cell, which is self-supporting and self-governing. It is a living entity, an indivisible unit, exhibiting and displaying all those characteristics associated with the larger plants, which are, after all, simply a collection of these cellular units wherein a division of labour has taken place, and in which, owing to centralisation leading to economy of space, each cell or group of cells has been given a separate function to carry out and in consequence has become modified in relation to its particular set of duties. Such division of labour is one of the leading features in the organisation of any multicellular plant; even an ordinary green leaf, which I will deal with in the next article, serves admirably to illustrate the general principle. G. C. TAYLOR.

GARDEN TECHNIQUE

Notes on the Technical Side of the Garden and the Cultivation of Plants.

GREENHOUSE

GROWING FOLIAGE TO MIX WITH FLOWERS.

FLOWERS, whether they are grown to be cut and placed in vases in a dwelling house, or to develop and fade on the plants for the embellishment of the greenhouse or conservatory, always look more charming when associated with suitable foliage. I am confining my remarks, in this note, to green foliage. Smilax, usually grown in a temperate house, may be successfully grown in a cool one in the southern counties. I have not had this experience myself, but I was assured, quite recently, by a gardener in this district that the plants would survive several degrees of frost without injury. Except as an experiment I would not grow the plants outside; but there are many walls in greenhouses suitable for it, and these may be quickly covered by healthy plants grown in a rich sandy loam and a small quantity of peat. The foliage makes a splendid permanent background, and it is always available for cutting. Another splendid cool house plant is Asparagus Sprengeri, which requires a rich sandy soil and plenty of moisture. Fine plants may be grown at the side of the path under the stage; also in baskets and pots. Asparagus is a more refined plant and requires a little more heat. Fern, Pteris tremula, planted out in greenhouse or conservatory borders, will supply a great many fronds for cutting. The maidenhair, Adiantum cuneatum, does best in pots, and both will thrive in fibrous loam and leaf-soil. For the sake of the foliage alone, it is worth while potting up now a few old plants of Spiræa japonica, the leaves will then be available in spring.—G.

PRUNING YOUNG VINES AND THOSE HAVING OLD SPURS.

I FEEL quite sure that many readers who have not had much experience in the pruning of vines will appreciate a few hints on the subject. Very much depends on the way the pruning is done; the young vine may be partly spoiled from forming a true, well balanced rod by wrong pruning, and old spurs, too, may be left to become worse every year unless the pruning is correct. A young vine, having made a year's growth after being planted in its permanent border, should be so pruned that the branches will be, approximately, 2ft. apart and placed alternately on both sides of the main rod. Whether one or a houseful of vines is to be dealt with, this system of building up the rod should be followed. The system of training a young vine during its first year's growth after planting has been explained in previous issues of THE GARDEN, and such vines will now be similar to the one shown in the sketch. The side shoots *a*, *b*

and *c* respectively, should be pruned as the cross lines denote. The buds *d*, *e* and *f* will develop, in due course, into side shoots if the leader is cut back at *g*, the top bud to form another leader. The remaining buds should be rubbed out as soon as they begin to grow. On a neglected old spur the best-placed shoot should be pruned as shown at *h*, and any smaller ones as shown at *i*, *i* cut out entirely. A bud similar to the one at *j* generally contains an embryo bunch of grapes, while a thin pointed bud, similar to the one at *k*, makes a wood shoot only.—GEORGE GARNER.

PRIMULINUS GLADIOLI IN POTS.

IT is not generally known that the graceful primulinus varieties of the gladiolus do quite well in pots. The compost should be a fairly rich one, consisting of fibrous loam to which a moderate addition of gritty sand has been added and up to 1 part in 5 of cow-manure which has been dried and rubbed through a sieve. Three or four corms are generally placed in an 8in. pot; the pots are watered and not plunged, but kept fairly cool while roots are forming. When growth really commences in earnest, plenty of water is required, and when buds appear liquid feeding may be resorted to. A pot of Woodcote is a gorgeous thing, and almost equally fine are the small-flowered Nydia, Psyche, Pansy and Maiden's Blush.—LANARKSHIRE.

TREES AND SHRUBS

SUMMER AND WINTER MULCHING.

[*The following contribution has been sent in by one of the best known gardeners. Although we do not entirely agree with Mr. Coutts' conclusions, as applied to shrubs such as rhododendrons, this note is interesting as a protest against indiscriminate mulching.*—ED.]

MULCHING, as is generally understood is the application of some protective or manurial material to the surface of the ground to prevent excessive evaporation, and to conserve the soil moisture during dry weather. When applied during the winter, it is usually of a protective nature, being used to protect the roots of newly planted or doubtfully hardy plants from the harmful effects of severe frost.

That this important garden operation is too often misunderstood and abused in practice is undoubtedly true. As a result of this abuse it is possible for much harm to result to the plants in question.

A better and wider understanding of the fact that a well aerated root run is essential for the well-being of most plants, would prevent much of the damage that results from the indiscriminate use of mulching material.

The injury may result from various causes, such as the too early application of mulching material, before the soil is properly warmed up. This may result in the roots being kept in a cold and stagnant condition right through out the summer. This is all the more likely to happen if the material is of the wrong kind and applied too thickly, and also if the summer proves wet and cold. I may add here that all material used for mulching should be of

Digitized by Google

such a loose, open character that it is easily permeable by air and warmth, such as strawy litter or partially decayed leaves. Many cultivators err in applying the mulching material too thickly. The ideal application should be just a mere sprinkling, even if it should be necessary to renew it later on in the season, but under our climatic conditions this is not usually necessary, and even with ideal material it should never exceed 3ins. in depth.

Before a mulch is applied, the ground, wherever possible, should be stirred to the depth of several inches with a digging fork. This will ensure the aeration of the soil for a short time. Much damage may result in various ways from too heavy applications of mulching material, apart from preventing the proper aeration of the soil, which in itself is serious enough. One of the main faults is that it soon induces sour, acid conditions, which is fatal to a healthy root system. Again, the material is often piled up round the stem of the plants to a depth of six or more inches ; this, in the case of woody plants often proves fatal, unless the mulch is of a very light and loose nature. I have in my experience observed much damage, ill-health and even death result from this practice. For example, I have seen many rhododendrons—and here I include azaleas—injured and often killed by too deep planting and the application of too much mulching material. In this case many cultivators imagine that rhododendrons will throw out fresh roots from the stem into the mulching material. This is quite true, if they are given time to do so, but it is a slow and gradual process, and can only happen when a thin sprinkling of leaves is applied every year, and in this connection we would do well to observe what happens naturally where leaves fall or collect under plants of this class. The thin layer decays from year to year and gradually becomes filled with roots.

I only take the rhododendron as an example of what happens from an excess of mulching, because I have seen much harm result to this class of plant, but the same principle applies, more or less, to all plants.

Apart from conserving moisture and warmth, mulches which consist of stable litter, well decayed farmyard manure or leaves, have a definite manurial value, and are usually applied for this purpose, as well as for conserving soil moisture. Mulches are commonly applied to fruit trees and vegetable crops with the definite idea of supplying manure to the respective crops during critical periods of their growth. Provided the material is of a suitable character and properly applied there is no doubt they have a definite manurial value. In mulches of this kind the manurial constituents are either gradually washed into the soil by rain, or if applied in dry weather, it is advisable to give a heavy watering after application.

By observation one is forced to the conclusion that much time and material are wasted by applying mulches in the wrong place. How often in the case of fruit and other trees do we see it applied to a small area just round the stem of the tree, where it can do little or no good, for we may take it for granted that in the case of established trees the roots that matter are much farther afield. When applied for purely protective purposes the material may have no manurial value; such material may consist of a thin layer of straw, dry bracken, coconut fibre, finely sifted peat moss litter or ashes ; all these are excellent for the protection from frost of more or less tender bulbs and other plants.

Having dealt with the various materials generally used for mulching, I now turn to what, in my opinion, is the most valuable of all methods of mulching, that is, surface cultivation. After what is usually called a life experience in horticulture in various parts of the country, I have no hesitation in saying that this, in most cases is the simplest and best way of conserving soil moisture during dry weather: best because a layer of dry soil is an ideal mulch, and at the same time the soil is kept aerated, which for the health of the plant is just as important as conserving the moisture. It also serves a double purpose as weeds are kept down at the same time.

Thus, wherever the character of the crop permits of it, the surface soil should be kept stirred to a depth of about 3ins. This can be done by means of the Dutch hoe or by some of the excellent cultivators that are now in general use, the hoe breaking the capillary tubes, while the loose surface layer of soil prevents evaporation. I have seen collections of roses that were regularly mulched, both summer and winter, improve immensely in health when mulching was discontinued altogether, and the top 3ins. of the soil kept loose with the hoe or cultivator. It will thus be seen that valuable as mulching is in garden practice, it must be applied with intelligence or else much harm may result. This is, I know, a highly controversial subject and opinions differ very much among cultivators' as to the value of mulching, as well as to the time and method of applying it.—J. COUTTS.

FRUIT

THE PRUNING OF TRAINED HARDY FRUIT TREES.

TO many the work of pruning is a stumbling block, but before such a task is undertaken, each tree should be studied, and once its mode of fruit bearing is understood, the beginner is less liable to make mistakes. Among the objects of pruning are the thinning and removal of all shoots not required for the future welfare of the tree, the cutting out of all decayed and diseased growths, and regulating the branches so that plenty of light and air can reach all parts of the tree. The pruning of hardy fruit trees is carried out from early December to February.

Among the fruits trained on walls, fences, arches, and by the side of garden walks, are apples, cherries, plums, pears, apricots, peaches and nectarines. It is not often the apple is afforded the protection of a wall, but good dessert varieties are sometimes grown as cordons. Until the allotted space is filled the main growth is allowed to develop and at the winter pruning it is cut back to six buds, while the remaining shoots are reduced to three or four buds. The same procedure is adopted with cordons trained over arches, or on wire supports. A bush tree, and a pyramid require much the same treatment ; extension shoots being cut back about half or one third their length, and the other growths to four buds. Any shoots not needed must be removed, or the tree will eventually become overcrowded. The cherry is best grown on walls in a private garden, and fan-trained trees are usually chosen. The object is to secure a well balanced specimen, and during the time the tree is covering its space the leading shoots are allowed to develop about 16ins. or 20ins., the necessary cutting back being performed in winter. The side shoots are pinched during the summer months and further reduced at the winter pruning to three or four buds. Any weak growths that are likely to produce overcrowding must be cut out at their base.

The Morello cherry requires different pruning from that of the sweet cherry, inasmuch as fruit is borne on growths of the previous summer. These shoots are tied in, and older wood is removed much in the same way as with peaches and nectarines.

The two first mentioned are largely grown under glass, but they are a success outside. Disbudding early in the season plays an important part with peaches and nectarines, and if this is done correctly little pruning will be needed in winter. This consists in cutting out old wood, so that the new shoots when tied in will be about 4ins. apart. All growths that push outwards from the wall must be removed, which is best carried out in summer.

The plum is quite hardy, but the finest varieties are often grown on walls, the fan-trained trees being the best. Every effort should be made to keep the bottom of the tree well furnished with healthy growth, remembering that there will always be plenty at the top. The main or leading branches are shortened about one-third of their length until the trees have filled their allotted space, when it will be necessary to cut them back much more severely. All the side growths that will not upset the balance or shape of the tree are pinched back to about seven leaves in July, and at the winter pruning cut down to three buds. Any badly placed shoots of all trained trees should be removed early in the season, and in the case of plums it ought to be borne in mind that growth of medium size is more profitable than that which is very robust. A certain amount of disbudding will be beneficial in the spring, if carried out with the future welfare of the tree in mind.

Pears are often grown as cordons and fan-shaped trees, on walls or on wires stretched alongside the garden paths or walks. Their treatment in regard to pruning is much the same as the apple. Cordon trees should be trained obliquely, and occasionally such examples become very vigorous, producing a quantity of rank wood and little or no fruit. Here it will be necessary to root-prune, and with small trees it is best to lift them, cutting back all the thick roots and retaining as many fibrous roots as possible. When re-planting do not bury the roots too deeply, and a little fresh loam and mortar rubble can be added with advantage. Make the soil quite firm, and do not render the tree fast to the wires until the earth has settled down.

Apricots are not grown to any extent and the less use made of the knife the better. Consequently the pruning, pinching and disbudding are spread over the summer months, and if such work is carried out judiciously, there will be little to do in winter. The best shoots are tied in about July, and the winter pruning is carried out directly the leaves fall. All side growths are reduced and badly placed shoots may be cut out.—T. W. B.

MISCELLANEOUS

THE USE AND ABUSE OF LIME.

THERE is, perhaps, no more valuable asset to the gardener than lime, and yet it is surprising how often, for general purposes, its correct uses are misunderstood. There are many whose sole prescription for practically all garden ailments consists of a good dressing of this substance in some form or other, in spite of the fact that, on many soils, constant overdoses of lime are likely to be injurious rather than helpful. Although satisfactory results are unobtainable without the presence of a certain quantity of free lime in the soil, lime in itself is not a fertiliser. It tends to sweeten a sour soil and is certainly of great assistance in lightening heavy ground and making it more workable. To apply wholesale quantities to ground that is already well supplied with lime is certainly a wasteful procedure, quite apart from the possibility of harmful after-effects. A very simple test can be made to ascertain whether lime is present in any particular spot. Take a small quantity of the soil and after mixing it with water in a glass jar to the consistency of paste, pour into the mixture a little hydrochloric acid. If the liquid bubbles freely there is sufficient lime in the soil, while its

Digitized by Google

proportionate deficiency is shown by the absence or feeble nature of the effervescence. If required, a good dressing of lime can then be given, and, under ordinary circumstances, further applications should not be required for two or three years. The best time for such a dressing is either in winter or early spring, when the ground is free from crops and before other fertilisers are applied.—J. C.

FERN GARDENS.

NO rock garden is really complete without a certain proportion of it is allotted to ferns. Hardy ferns produce so pleasing an effect that to omit them is only to half finish the rockery. Whenever one's mind pictures a beautiful range of rocks in some valley, our imagination at once reminds us of the lovely ferns growing out of the crevices.

The main principle to be borne in mind in planting is proper drainage, for nothing is more detrimental to ferns than stagnation. Constant damp is ruinous. It is, therefore, desirable that plenty of broken bricks and similar rubbish should be used as a foundation to the rockery beneath the soil, which should be raised as a preliminary to embedding rocks or burrs to form the rockery proper. Of course, when planning a fern garden, much will depend on the local surroundings; ferns, being naturally fond of shady places, will need to be sheltered from wind and burning sunshine, so that they can display their fronds to full advantage. It is a good plan, before starting to plant, to study the various peculiarities of the different ferns. Thus, the common polypody and all the spleenworts can be used for covering bare walls; while for the small crevices in the rockery, such ferns as the polypodies and the limestone will make quite an effective display. The royal fern, the lady fern and Osmunda regalis, being all lovers of moisture, should be planted at the base of the rockwork.

For the general filling in of space, such ferns as the lastreas and polystichums will be the most suitable, as they require more root room than any of the other sorts.

A pleasing feature that should be introduced into the rockery is a moraine, for it is admirably suitable for showing off ferns effectively.

The best position is on a site that is slightly sloping. Dig out the soil to a depth of about 2½ft., and fill in the bottom with some broken brickbats for a foundation, to a depth of 9ins.; over this, fill in a layer of small stones about 3ins. deep, and fill in the rest of the space with a mixture of soil and stone chippings. When the ferns have become established, the moraine will look well for years without much attention, save keeping tidy.—G. BARTON.

BOOK REVIEW

GARDENING, as with the majority of subjects, becomes an increasingly complex subject as the years go on, and the reasons are not far to seek. The arrival of hundreds of new plants from different corners of the world, and the consequent rearrangement of our ideas regarding the formation of different types of garden and the plants to be included in them, together with improved and better methods of cultivation and propagation in all branches of the subject, have, within the last fifteen to twenty years, created the need for a comprehensive and up-to-date work on practical horticulture. True, literature has, to a certain extent, kept pace with the growing confines of the subject and has given us numerous volumes, both large and small, dealing with every particular aspect. The present work "The Gardener's Assistant," edited by William Watson and published in six volumes by the Gresham Publishing Company, Limited, Chandos Street, W.C.2, price 12s. 6d. per volume, supplies the need for a sound and comprehensive guide to practical gardening. This new edition, the fourth since Thompson published the first edition of it in 1859, is the outcome of many years of labour on the part of the numerous contributors, whose names, be it added, stand as testimony to the excellence and accuracy of the subject matter. The three previous editions have already gained for the work a high reputation in the gardening world, which will be easily maintained, if not surpassed, by the present one.

All branches and aspects of practical and scientific horticulture are treated within its pages. It may be said that it presents, in what is, after all, comparatively little space, the sum total of our gardening knowledge to date. The work is, indeed, too large to detail all that is dealt with, but the above may serve to indicate the wide field covered by the six volumes.

The method of arrangement of the subject matter is to be commended. It is thoroughly practical in its aim. To each branch, together with its allied subjects, is devoted a definite section, and these latter are correlated by means of cross references. In addition, there is a comprehensive index which will be found of great service. The information given on all points, from the most important items to the most minute details, is clear and concise, and easily found and sorted out from the mass of material presented.

It appeals to all who garden, professional and amateur. The former will find it of the greatest possible use in supplying a ready and satisfactory answer to all those detailed questions which crop up with marked persistency in the carrying out of gardening duties. It is full of counsel and advice in all practical matters which the working gardener should be only too pleased to consult and follow. To the amateur, it comes, like the Waverley Pen, as a boon and a blessing. There is nothing forbidding in its appearance or in the text. All the simple details as well as the intricacies of the many and varied gardening operations are fully given and described, so that the mere tyro will find little difficulty in following the instructions. Adequate descriptions of each and all classes of plants are fully and lucidly given, together with cultural notes and the position that they should occupy in the garden. There is yet another class of gardener who will find it lives up to its title, namely, the commercial or market gardener. The many what might be termed useful "tips" in the various sections he will find convincing, even when regarded from his standpoint. All nurserymen and trade growers will discover in its pages much to interest them. It may even assist them in their own specialised line.

As has already been said, it is a work for all garden lovers. The volumes are well and clearly printed and are profusely illustrated by means of a series of full-page coloured plates, together with numerous fine half-tone reproductions and many line drawings, serving to illustrate more clearly explanations in the text. It appears remarkably free from errors in plant names, which in itself is an undoubted asset in a work of this description, and although it does not include some of the latest introductions to our gardens, such omissions are of no account, considering the size and scope of this excellent work. G. C. T.

TRADE NOTES.

At the recent Birmingham Chrysanthemum Society's Show Messrs. Webbs of Stourbridge staged a fine exhibit of vegetables, comprising some seventy-five dishes, which was awarded a large gold medal. Prominent features of the display were fine dishes of Webbs, Champion Prize leek, Perfection Pink and Giant White celery, Autumn Queen cauliflower, Advancer savoy, Reliance Globe beet, Marrowfat parsnip, and Standard and Defiance Intermediate carrots. The well arranged stand is shown in the accompanying illustration.

MESSRS. WEBB'S GOLD MEDAL EXHIBIT OF VEGETABLES AT BIRMINGHAM.

The majority of gardeners have all a liking for "my Lady Nicotine," and at this season of the year there is no more suitable present than a box of Player's No. 3 Virginia cigarettes. A box of these along with a book on gardening will prove most acceptable and seasonable. Messrs. Player's cigarettes are sufficiently well known with some forty years' reputation behind them, and "No. 3" still further establishes their quality and excellence. They are made from the choicest Virginia tobacco, which all gardeners will enjoy.

THREE NEW SEEDLING POTATOES.

All vegetable enthusiasts will be interested in three new seedling potatoes which are being offered by Messrs. Garden Supplies, Limited, Liverpool. Two of these, Keay's Champion and Sefton Wonder, are immune to wart and black scab. The former, essentially a farmer's potato, is a seedling from Majestic crossed with a red kidney variety and resembles King Edward in shape a

Digitized by Google

colour. It has the reputation of being a heavy cropper in poor soils. The latter, Sefton Wonder, has been raised from Great Scot, and is classed by the Board of Agriculture as an immune second early. It is earlier than Great Scot, a heavier cropper and with better keeping qualities. The third variety is Glen Ericht, which has already won its spurs in a competition open to members of the L. M. & S. Railway. More of this variety will probably be heard in the future.

An excellent and useful companion to the Spade Boot Scraper, which is already on the market, has appeared in the Spade Boot Brush, which is equally to be recommended as a preventive against the bringing in of mud into the house after the gardening duties have been completed. It has many good points, which can be seen in the accompanying illustration. The brush itself is raised off the ground by three iron feet, and this enables the top part of the boot to be cleaned more easily, whereas with the old type there was always a difficulty in cleaning this part. The bristles of the brush are of good quality and not liable to rot if left out in the rain. An additional advantage is that the mud falls off automatically, thus not clogging the bristles. They are certainly the most up-to-date appliances for cleaning muddy boots, and are admirable for use after gardening. They are obtainable from any of the London stores or direct from "Spade Scrapers," Wappenham, Towcester, Northants. The price is moderate and will be found to compare favourably with that of the old type.

NORWICH CHRYSANTHEMUM SHOW

THIS three day fixture was held on November 19th, 20th, and 21st, in St. Andrew's Hall, Norwich. The chrysanthemums and other exhibits were well up to any previous standard, indeed, in the class for thirty-six blooms there were to be seen even better blooms than usual. The best Japanese bloom in the show was a magnificent specimen of Mrs. G. Carpenter, included in an exhibit staged by Mr. Bentley, Langley Park Gardens, Norfolk. The Norwich Corporation had a very fine group of pot chrysanthemums and foliage plants; for this Captain Sandys Winsch, the Parks Superintendent, received many personal congratulations. The Misses McLintock, Catton Grove, Norwich, also staged a beautiful group, wherein they had endeavoured to convey an artistic impression of red, terra-cotta and gold. There was keen competition in the hall-vase and decorated basket sections. In the latter, Mr. Gordon Lang, Plumstead, deserved the honour of first place, with a most artistic production.

In other sections a feature of note was the collection of berried plants from the Norwich Corporation, which has now taken over Earlham Hall, where the late Mr. Sydney Morris established such a choice collection of these shrubs.

Begonias made a very bright display, especially the newer hybrid, winter-flowering types. Primulas were represented by four distinct types, malacoides, kewensis, obconica and sinensis, all carrying a profusion of flowers. An interesting feature was a display of seedling nerine blooms, staged by Mr. Sam High, gardener to Mr. J. A. Christie, M.P., Framingham. Their brightness seemed to attract special attention.

In the fruit section the outstanding feature was the wonderful display of apples. The colour and quality left nothing to be desired. There were over 100 entries and many classes were for twelve, six and three dishes.

The classes for grapes were nearly all "topped" in the prize awards by the splendid examples staged by Mr. William Allan (Gunton Park Gardens).

The trade growers helped materially in the attractiveness and educational side of the show.

Messrs. Daniels, Bros., Limited, Norwich, had made a feature of apples from their fruit nursery at Tunstead, and vegetables from their pedigree stocks. Messrs. Allwood Bros. and Mr. C. Engelmann had displays of carnations; Messrs. Keith, Luxford and Co., chrysanthemums; Messrs. Clibrans, cyclamen; Messrs. A. Reeves and Co., Catton, Norwich, fruit and fruit trees; and Messrs. Suttons a fine array of vegetables.

Five Pounds for Articles on Carnations.—The President of the British Carnation Society offers the following prizes for the best articles on Perpetual-flowering Carnations: First prize, £2 10s.; second prize, £1 10s.; third prize, £1. Open to amateurs, gardeners and nursery employees who are members or who may become members of the British Carnation Society. The treatment of the subject is left entirely open, allowing members to write on as many phases of the carnation, its culture and decorative value, as they desire. Papers to contain not fewer than 1,000 and not more than 1,500 words, to be in the hands of the hon. secretary, Mr. P. F. Bunyard, 57, Kidderminster Road, Croydon, before February 28th, 1926, under a *nom de plume*; a separate sealed envelope to contain the name and address of the writer. The papers will be judged by the editor of the Society's Bulletin, assisted by two gentlemen appointed by the committee. The three best will be published in the Bulletin, others possessing merit may also be published in whole or part.

CATALOGUE RECEIVED

Messrs. Hillier and Sons, Winchester.—Hardy Trees and Shrubs, including an exceptionally fine collection of new Chinese species, which will attract all shrub lovers. Quite a number of rare species of rhododendrons is also offered.

CORRECTION.

We much regret an error which appeared in Messrs. Carson and Son's advertisement on page iii. The text should have read as follows: "'Vitrolite,' superior to white lead paint, 18/6 per gallon." No inconvenience has been caused, we trust, through this mistake.

It may be of interest to many of our readers to learn that Mr. Percy S. Cane has returned from America, where he has been designing many gardens, and has taken up residence again at Westminster Palace Gardens.

— *An Unique Offer* —

New and Rare

RHODODENDRONS

HILLIER & SONS

Tree Specialists, WINCHESTER

Including many of the late Mr. REGINALD FARRER'S and the Messrs. E. H. WILSON'S, G. FORREST'S, F. KINGDON WARD'S and **New Chinese Species**; also **Himalayan** and other varieties from private collections; consequently they cannot be seen in our Nurseries. These species vary from dwarf alpine gems for the rock garden to those of giant tree-like stature and magnificent leafage.

The plants are from seed and have been several times transplanted, and are of unusual quality and bushiness.

Some of the Species we can supply by the hundred, and shall be pleased to quote special rates for a quantity.

WRITE FOR DESCRIPTIVE PRICE LIST.

THE DOG: MAN'S FIRMEST FRIEND.—How to choose and care for him, by A. CROXTON SMITH. A copy of this helpful booklet on the housing, breeding, feeding and care of dogs will be sent post free on receipt of 11d., addressed to The Manager, "COUNTRY LIFE," LIMITED, 20, Tavistock Street, Covent Garden, W.C.2.

WHY ORCHIDS?

Why grow Orchids? Because many orchids are of easy cultivation. Because the flowers last longer than many others. Because once you have the plants, they have not to be replaced each year like other plants.

We make a special offer of easily grown Orchids for beginners.

THE END OF THE YEAR

I LUNCHED the other day with a friend, an author who makes his bread and butter by writing short stories for the magazines, and very good stories they are. I found him shivering and very cross. His last three days had been spent in working out the plots of a series of summer stories where beautiful maidens loll about in punts and the villain is overheated in a thin silk shirt and a pair of Oxford trousers. A writer on horticulture has to have a certain amount of imagination, but now and then he can write on subjects of immediate interest and so find himself in an appropriate mood. At the present moment I could write an authoritative article on the importance of proper heating in a stove house, but that is, perhaps, beside the point.

At the time of writing we are experiencing the most seasonable winter weather that we have had for many years. It is true that it retards much important work in the garden. A great deal that ought to be done is half completed or not started. Still a hard winter was badly needed and should do a great deal of good in all gardens. Now that the year is drawing to a close I think that all gardeners can congratulate themselves on the results of the past year. On the whole it has been a good year for gardens.

When, in the distant future, the history of present day gardening comes to be written, I believe that the authors will discover that the years 1921–31 have shown the greatest advance in horticulture that has ever been seen. Unlike other changes, the transition since the war has been sudden. Many of the great gardens of the past have disappeared or have been so curtailed as to lose their importance. Luckily, the professional gardeners survive, for they make up a magnificent body of men, hard-working, practical, knowledgeable. On the other hand they have to work in a more confined and intimate area and so evolution is taking place among them. Where the post-war change is most noticeable is in the enormous new class of amateur gardeners that is coming into being. There have been amateurs in the past, but they have usually played at gardening and left the hard work to others; now the amateur works as hard in his spare time as the professional. He not only enjoys, but plays a large part in the well-being of his garden. Many cannot afford to hire labour; the wise ones cut their cloth accordingly, and the ambitious may try too much, but even they are running along the right lines.

The formation of this large class of enthusiasts has raised the standard of the amateur horticulturist enormously. They are keen to learn the best methods, they willingly acknowledge faults into which their inexperience has led them, they are ready to take advice, they are willing to pass on their experiences to others. They form a fresh driving force that should be of immense assistance to horticulture for many years to come.

This new type of horticulturist is not satisfied with knowing a fact; he wants to know the reason for all he does. He wants the best and sees that he gets it. That is one of the reasons why THE GARDEN makes such an appeal to all keen, intelligent gardeners. We try to make the paper a clearing-house for all matters that deal with the highways and byways of horticulture. In its new and more popular form, we hope that THE GARDEN appeals alike to the specialist in some particular plant and to the keen amateur who desires above all to make his garden as beautiful as possible throughout most of the year. We try our best to keep away from the stereotyped form of gardening article and to make the points we wish to emphasise as palatable reading as possible. In order to do this we have made three main features in the paper, Notes of the Week, Correspondence and Notes on Garden Technique. They all have an excellent bearing on the importance of co-operation between the reader and the paper, which we try to emphasise as much as possible. We are pleased to see how these three features in particular are becoming more and more appreciated by our readers, as is shown by the constant messages of congratulation that we receive. I hope that during the coming year they will become even more prominent, for, in truth, they are run by readers for readers; the editorial staff merely sorts them out and arranges them.

As this is the season for giving and receiving, may I point out that there are few more acceptable presents than a year's subscription to THE GARDEN. This subscription will ensure a pleasant gift to the recipient and will also make a Christmas present for us. The more readers we obtain, the more we can give in return and the greater will be the value of the pages of THE GARDEN as *the* clearing-house for all gardening information.

THE DECORATION OF PAVED GARDEN PATHS

THE present-day fashion for paved paths in the garden, when not overdone, gives just that finishing touch to set off the flowers in the beds and borders. There are two methods of laying the stones in such paths. Architects, who are more and more frequently designing the gardens to go with their houses, seem to favour properly squared stones set in cement according to a geometrical design, the plans for which have been carefully drawn out in the office. This method has one great advantage over all others in that it is impossible for weeds to spring up between the stones, the paths, too, being perfectly level, are excellent to walk upon.

The other method, usually referred to as "crazy paving," gives the gardener a much greater opportunity for exercising his originality. Here the stones are laid in earth just anyhow with little spaces at the junctures of every two or three of them.

The straight edge of a path set in cement can be broken by means of plants of a decumbent habit, such as Veronica rupestris, which forms fine little green tufts encroaching on the stones, tufts which in due season will give place to lovely patches of blue. Nepeta Mussini with its pale lavender spikes is another low-growing herb which seems to have been created for this purpose.

A sunk birds'-bath, too, may be constructed at the juncture of two paths or at the end of an alley. Formally clipped trees of box, yew or bay, either in tubs or in spaces left between the stones, form an admirable decoration for paths of this kind.

But it is in the decoration of crazy paving that the amateur gardener has his chance of showing his knowlege of the habits of the various plants which are suitable for the decoration of such paths.

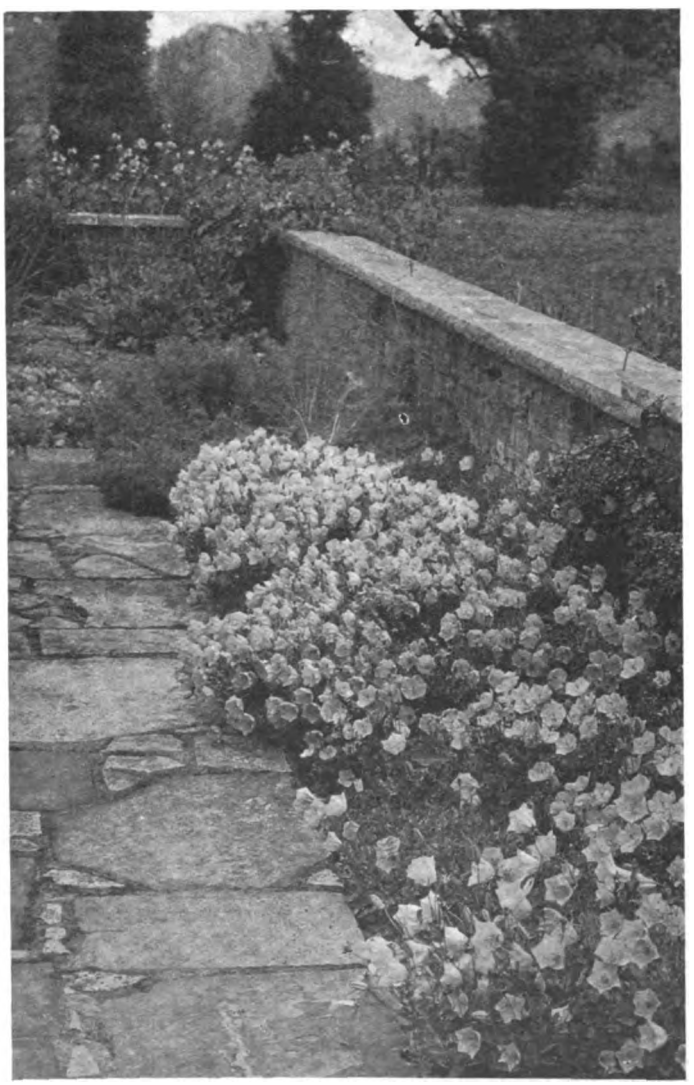
The centre of a path leading from one part of the garden to another or from the roadway to the house traversed daily by many who are not any too particular where they tread should always be kept perfectly clear. The edges alone of such a path should be adorned, and even then only by very close-growing plants, which show but little objection to the occasional pressure of an erring foot. Such plants are the acænas, both the one with silvery grey foliage and that with coppery coloured leaves. These produce charming little flowers in June, which, however, can hardly be considered exactly conspicuous. The close-growing thymes are quite suitable too, emitting a delightful odour when trodden on, and some of them produce dense patches of the most gorgeous wine-coloured flowers. They creep over the stones and partly cover them in the most delightful manner, and their flowers form a pleasant contrast with the colour of the stones. A really hot summer seems to suit them admirably and they show no signs of distress from lack of moisture.

For a shady part of the path, and particularly where it is a little moist, we have Arenaria balearica with its minute dark green leaves studded in June and July with tiny white star-like flowers supported on very short stems. Then there is a little oxalis with dark red leaves which will clothe the stones along the edge of a path. It has charming little yellow flowers which contrast well with the red leaves and set their seed very freely. In fact, if not kept well within bounds, this plant may become a perfect nuisance. We must not forget violet cress with the wonderful Latin name, Ionopsidium, which usually causes consternation to the indiscreet enquirer as to the name of this charming little plant. Sown with a little sand in the crevices between the stones, it will flower a few weeks later, set its seed, and the seedlings will flower again before the summer is past. This little annual, which comcs to us from Portugal, has praiseworthy manners and knows how to keep its place.

The stonecrops, too, both the yellow and the white, make a splendid decoration planted here and there along the edge of a path. There is a very close-growing one with silvery grey leaves, but, unfortunately, this seems to be very slow growing.

Where crazy paving is used for purely decorative purposes, as round a sundial, for instance, or a garden figure on a pedestal, there is no reason why every little crevice should not contain some plant, provided always that a clear space be left on the north of the dial from which the time may be read without casting a shadow on the ancient timepiece. Such places are not intended for the passage of careless feet, and choicer plants with a more pronounced bias against being trodden upon may here be selected. And there are a great number of such plants from which we can make our selection. Here is the place for hummocks of thrift to rise among the stones. Little mossy mounds of various saxifrages, which will be studded in their due season with flowers of pink, white, red and yellow. Then we can have lovely little tuffets of the saxifrages of the London pride group, from which the little spotted flowers will spring on their slender stems. A fine yellow oxalis with dark green shamrock leaves will form a pleasant contrast to a wine-coloured thyme creeping among the stones. A seedling viola, a plant or two of self-sown forget-me-not, a Tom Thumb nasturtium, a coloured primrose, all help to add colour to what is virtually a rock garden in one plane. Later on a dwarf campanula may grow between the stones and open its dainty bells of white or mauve.

The base of the sundial, be this round or square, may be set off by a narrow bed some 3ins. or 4ins. across, bounded on the one side by the base of the dial on the other by the crazy paving. In it we can plant a profusion of the smaller spring bulbs: chionodoxas, scillas, grape hyacinths and crocuses. We can set it thick with little pink daisies of the Dresden china type. We can sow it with nemophila, phacelia or blood-red dwarf nasturtiums, each in its proper season forming a fairy ring of flowers almost all the year round.



THE DWARF CAMPANULAS ARE MOST ATTRACTIVE WHEN MASSED BY THE PATHSIDE.

AN EFFECTIVE DECORATION OF GARDEN STEPS.

Then there are sure to be steps in the paths where the garden is not all on one level, and what garden ever is ? These, too, must be suitably decorated, and we must not forget that the primary object of steps is to take one up or down the paths. It is, therefore, only the edges or the corner angles which should be planted, though occasionally Nature will set a little plant close to the bottom step between it and the path. Clothing the sides of the steps there may be planted two fairly large clumps of a dwarf mauve campanula set off by a large plant of the half-hardy Oxalis rosea, which lives out of doors all the year round in this mild climate. Along the bottom of the granite steps and interspersed among the larger masses of colour, Welsh poppies can be allowed to sow themselves. They give just that added touch of clear yellow which is so necessary to enhance the colour scheme.

For the corners of the steps perhaps we may venture on a little fern, or a house-leek or two, but they must be well tucked in so as to avoid a kick from some ascending boot.

For those with a passion for blue—and does any other colour look so well against the stones ?—the Apennine anemone is admirably adapted for the decoration of a shady corner of the steps. Planted with common thyme, the flowers will find their way to the light, and when they are gone the thyme is there to clothe the edge of the steps and exhale its lovely scent when brushed by passers-by. Lithospermum prostratum makes a gorgeous gown of royal blue with which to deck the steps in a sunny part of the garden. Should the steps run between boundary walls, snow-on-the-mountain and aubrietia, which the West Country cottager calls blue snow-on-the-mountain, together with cerastium, form a trio of quite common plants for the decoration of the sides of the steps.

When the steps are very broad and shallow, there is no better edging for them than violas of all colours. The impression thus obtained of hundreds of these little flowers rising one above the other, as on a show bench, is wonderfully effective. This is especially the case if the violas are allowed to continue along the path, which should have a slight curve at the top of the steps. The violas will grow over the edge of the stones and form a coloured riband along the side of the path.

It would be futile to pretend that such floral paths as are here described are no trouble to maintain ; but surely it is worth while to spend a little time on the decoration of the paved paths which we are continually using as we pursue our way through the garden. EDWARD CAHEN.

THE BIRCHES

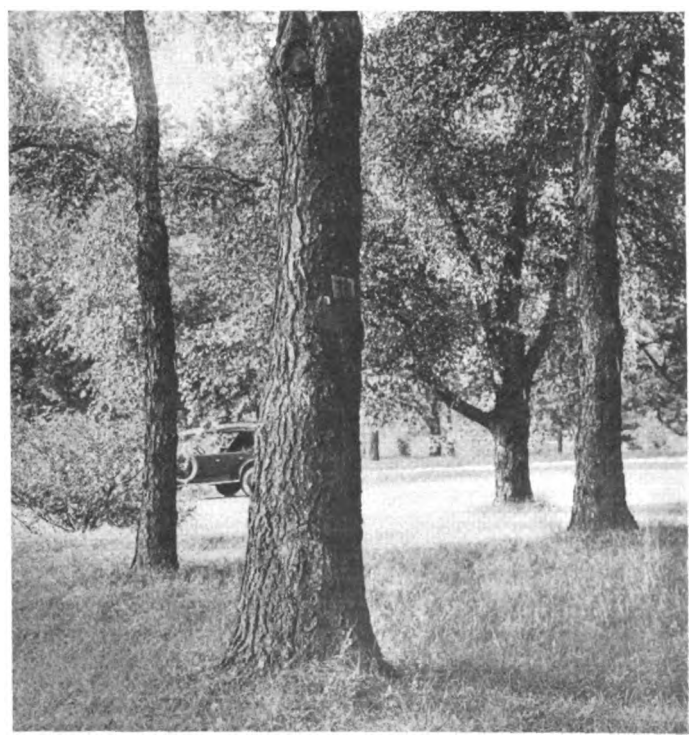
BY E. H. WILSON.

(*Continued from page* 683).

ONE of the most conspicuous and characteristic trees of the mixed forests of northern Korea is B. costata, with white papery bark. It grows from 40ft. to 80ft. tall, and has a trunk from 3ft. to 8ft. in girth, which on old trees is clad with pale grey, loose, scaly bark. The leaves are ovate, long-pointed, sharply toothed, lustrous green, with prominent nerves ; the fruit is erect, stout, barrel-shaped, with long pointed scales. This birch has been much misunderstood and often confused with the black birch of Japan (B. grossa) and with B. Ermani, both very different species. It is doubtful if it ever had been in cultivation until I sent seeds to the Arnold Arboretum in 1918 from Korea. With its polished foliage and rugged trunk it is a decidedly ornamental tree.

Another little-known birch is the Japanese B. corylifolia, with smooth, fine, silvery grey bark, broad ovate to obovate, coarsely toothed leaves with prominent veins, grey on the underside and clothed when young with silky appressed pale grey hairs. The fruit is cylindric, stout and ascending, with very long pointed scales. The leaves, except for their large teeth, suggest those of the European beech, but the important point is that the twigs have an aromatic odour like those of the American sweet birch (B. lenta) ; this is the only birch with white bark that has this peculiarity. This distinct and interesting birch is fairly common on volcanic soils in central and northern Japan, but I have not seen it wild elsewhere. I introduced it in 1914, but it has failed to make itself at home in the Arnold Arboretum.

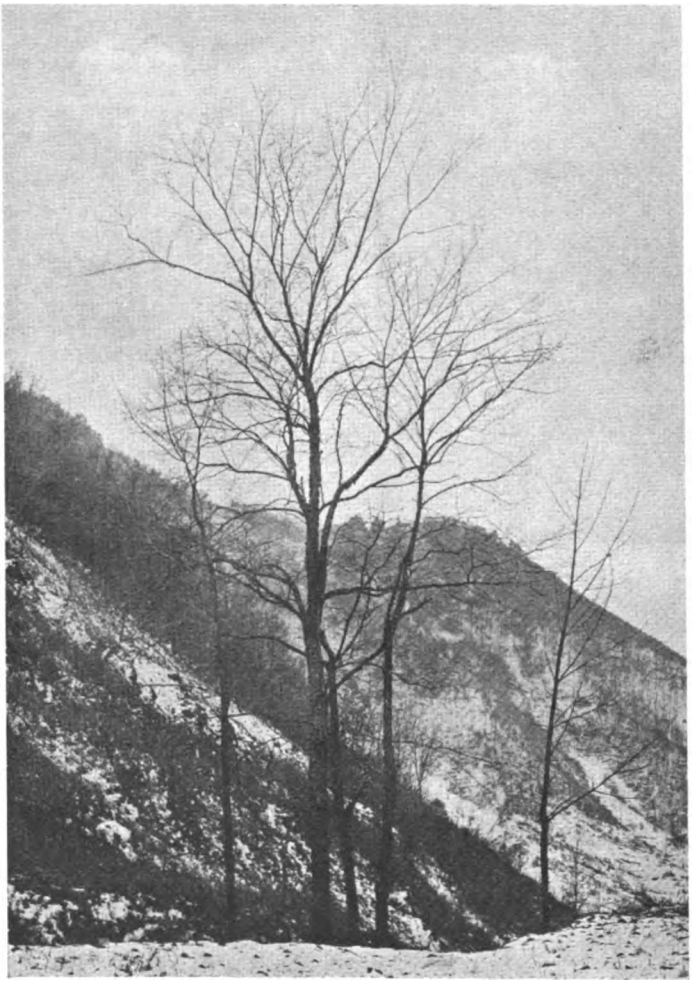
A lovely birch, abundant on the highest mountains of central China, is B. albosinensis. It is a tree up to 80ft. tall, with a clean trunk, sometimes 10ft. in girth, which grows mixed with other deciduous-leaved trees, though occasionally it forms pure woods. The bark is singularly lovely, being a rich orange-red



BETULA NIGRA, THE RIVER BIRCH.

Digitized by Google

or orange-brown, and peels off in sheets each no thicker than fine tissue paper, and each successive sheet is clothed with a white glaucous bloom. It is in cultivation from seeds I sent from China in 1910. For some unknown reason it has not grown well in the Arnold Arboretum, and I hope better fortune has attended it in British gardens, for it is a most captivating ornamental tree. A presumed variety (septentrionalis) is very common on the mountains of the Chino-Tibetan borderland, where it grows 100ft. tall, with trunks from 12ft. to 15ft. in girth. The bark varies from orange-brown on young trees to orange, orange-yellow or orange-grey on old trees. It exfoliates in thin sheets which persist as shaggy masses on old trunks and branches. The bark lacks the white glaucous bloom of the central China birch, and, in my opinion, it represents another species. It is my Nos. 900 and 900A. Whatever its identity, it is a most worthy tree, and from youth to middle age its smooth polished orange-brown bark is most attractive. The so-called B. utilis var. Prattii, which is growing in gardens under my seed Nos. 976, 990, 4089, 4087, 1138 and 4035, is, I consider, but another condition of this same birch. In the spring of 1909 I saw growing in the Botanic Garden at St. Petersburg a birch with the same characteristic bark, and I am sure it is my friend of the Chino-Tibetan forests. It was called B. utilis, and under this name several writers have referred to it. The authorities at the time could not tell me its origin, but I doubt not that Russian explorers had sent back the seed from the Tibetan marches. The true B. utilis is a Himalayan species introduced into England by Sir Joseph Hooker in 1849, but to this day remains a little-known tree. From what one can learn, it appears to be tender in Britain, and, moreover, there is a confusion with B. Jacquemontii not yet properly unravelled.



THE LOW-LEVEL BIRCH OF CENTRAL CHINA, B. LUMINIFERA.

The common low-level birch of central China is B. luminifera, which, under the name of B. alnoides var. pyrifolia, is growing in England from seeds that I collected. This has a firm, smooth, dark red-brown bark which becomes dull brown or even yellowish-grey on old trees. It is a common tree, rarely 75ft. tall, with a trunk from 3ft. to 8ft. in girth. The foliage varies a great deal in shape and serration, and the clustered catkins are often more than 3ins. long. It has not proved hardy in the Arnold Arboretum, but is growing well at Kew, where it promises to be a useful addition to the arboretum.

The red birch of northern Japan (B. Maximowiczii) has the largest leaves and longest catkins of all known hardy birches. In Hokkaido, where it is at its best, I have seen trees fully 100ft. tall, with a trunk 12ft. in girth and clean of branches for 50ft. and more. But such trees have a roundish, mop-like crown, grey-brown or grey unattractive bark split into long, broad, thin sheets which curl and cling to the tree in shaggy masses. The young vigorous trees are of open habit, with the trunk and principal branches clad with firm, smooth, snow-white bark. Introduced in 1893 into cultivation by Professor Sargent, this birch has proved a hardy, vigorous, quick-growing tree, distinct and markedly handsome.

A semi-aquatic birch and lover of rich alluvial soil is B. nigra, the river birch, abundant in the eastern United States from the Atlantic seaboard to west of the Mississippi River, and found in its greatest size in the lowlands of sub-tropical Florida. It is a large tree from 80ft. to 90ft. tall, with a trunk 15ft. in girth which divides some 10ft. to 20ft. above the ground into from two to several massive diverging limbs. The bark on young trees is shining light reddish brown and separates freely into large, thin papery scales which curl and remain on the tree for many years in shaggy masses. On the trunk of old trees the bark is fissured and broken on the surface into thick, closely appressed scales, dark red-brown in colour. This birch is most strikingly distinct and picturesque in appearance.

(To be continued.)

SUCCESS WITH GARDEN PEONIES

ONE of the most remarkable events in modern horticulture has been what one might well term the discovery of the herbaceous peony. This magnificent flower has been somewhat slow in coming to the fore, but is now firmly established in the affections of every garden enthusiast. After all, it was impossible that so beautiful a flower—perhaps our most beautiful perennial—could be neglected for ever.

In such a country as ours, with its many weather changes, no plant of questionable hardiness can attain widespread popularity, and surely its remarkable constitution must have been an important factor in the peony's rise to fame. "Hardy as a weed" is a term applied to not a few herbaceous plants, but to none can it be applied with more truth than to the peony. Frost, rain and wind seem unable to disturb the equanimity of the plant, and there is no doubt that it can be grown, and grown well, on a greater variety of soils, and in a greater variety of positions, than any other perennial. How much this means to those true flower lovers who, wherever they may be, strive to fashion for themselves a beautiful garden! Few of us are fortunate enough to possess ideal conditions of soil and aspect, but the many who have to plant under difficulties can at least console themselves with the thought that a garden in which peonies refuse to grow is hopeless indeed.

The plant, of course, has a preference, and this is for a good medium loam which has been trenched to a depth of about 2ft. Unless the soil is of exceptional fertility, it is advisable to incorporate with it some well decayed cow manure or leaf-mould as the trenching proceeds, for it must be remembered that the peony when planted should be allowed to remain undisturbed for five or six years. October is generally considered to be the best month for planting, but any time from that month until April is quite suitable, providing always that the weather be mild and the soil in a good, workable condition. With early planting, however, there is a possibility that many of the plants will flower the first summer, but with

Digitized by Google

later plantings this is uncertain. In any case, a lot of bloom will not be produced until the second year, as the peony does not establish itself so quickly as fibrous-rooted plants, and takes time to make itself thoroughly at home. A fair amount of room should be allowed between the plants—3ft. to 4ft. will not be too much, for they form large clumps in the course of two or three years. If an immediate effect is desired, the peonies may be planted 2ft. apart, and every alternate plant can be removed after the second or third year. Established plants will appreciate feeding from time to time, and it is a good plan to apply a dressing of well decayed manure each spring, forking it well in around the plants. In default of manure, bone-meal could be used with advantage, applying this at the rate of 4 oz. per square yard.

A strong point in the flower's favour is its suitability for house decoration. Here it need acknowledge no rival but the rose. The many exquisite tints which the art of the hybridist has produced make it possible to find shades which will harmonise with every scheme of interior decoration, and the long, sturdy stems upon which the huge flowers are so gracefully borne make the task of arranging them as easy at it is delightful. Fragrance, too, is not lacking, and it is a curious fact that while the latest varieties of roses and sweet peas seem to have sacrificed much of their scent for additional size and beauty of colouring, the delightful spices and honey perfume of the peony are most evident in some of the choicer sorts.

More important, perhaps, than its adaptability to decorative work is its great value in the garden. It would not be too much to say that not only is it impossible to have too many peonies, but it is also impossible to place them wrongly. There are innumerable ways in which this noble flower can be used. It should be found in gardens large and small, planted in beds and herbaceous borders, and massed boldly in the wild garden and park. Where space permits whole borders may be devoted to the flower with splendid effect. Two broad borders flanking a drive or a spacious grass walk would be a superb sight if planted entirely with peonies in their many beautiful colours. In a very large place it might be possible to form a separate garden for peonies. A little formal garden could be laid out on a stretch of level lawn and enclosed with yew hedge or trellis. Two flagged paths meeting in the middle at a sundial or bird bath would add to its charm, and the whole would form a delightful setting for the beds of peonies. From early spring when the first reddish shoots appeared through the soil, to the autumn, when the foliage assumed brilliant hues of orange, carmine and purple, the garden would never lack colour or interest, and in early summer, with the plants smothered with gorgeous flowers, the spectacle would be magnificent.

Better still, however, would be an informal arrangement of irregularly shaped groups in wood or park. One can imagine a woodland clearing of about a quarter of an acre in extent carpeted with emerald turf, and here and there bold groups of peonies, the tree growth around making an effective back-ground for the exquisite tints of the flowers.

It is possible to plant quite a number of things with the peonies, but while they can be associated very happily with most herbaceous plants, it is better, on the whole, to interplant mainly with bulbous subjects. Early spring colour can be obtained by introducing a few scillas and narcissi among the plants, and for summer and autumn effect such flowers as gladioli, montbretias and Galtonia candicans immediately suggest themselves. Lilies, too, look very well in the peony beds, and some of the best for this purpose would be LL. regale, Brownii, Henryi and pardalinum.

Turning to the question of the best varieties to grow, we realise that the old peonies of the cottage garden—charming as they were—have been rendered obsolete by the wonderful new kinds which have been raised in the past few years. The efforts of the leading nursery firms, particularly that of Messrs. Kelway and Son of Langport, Somerset, have produced some new sorts of great beauty.

The following selection will be found to include some of the finest varieties in commerce:

SINGLE VARIETIES.

E. ST. HILL, one of the largest single peonies, many flowers measuring 8½ins. across. Colour a deep rose pink, shaded white at the edges.

KELWAY'S GORGEOUS, a most brilliant salmon-rose, quite an uncommon colour. The flower is well shaped and the foliage very fine.

NELLIE, one of the finest single varieties in this colour, and very early flowering. Perhaps the largest of the single peonies.

PURE LOVE, very fine. A large pure white.

MAFEKING, bright scarlet-crimson. A very showy variety.

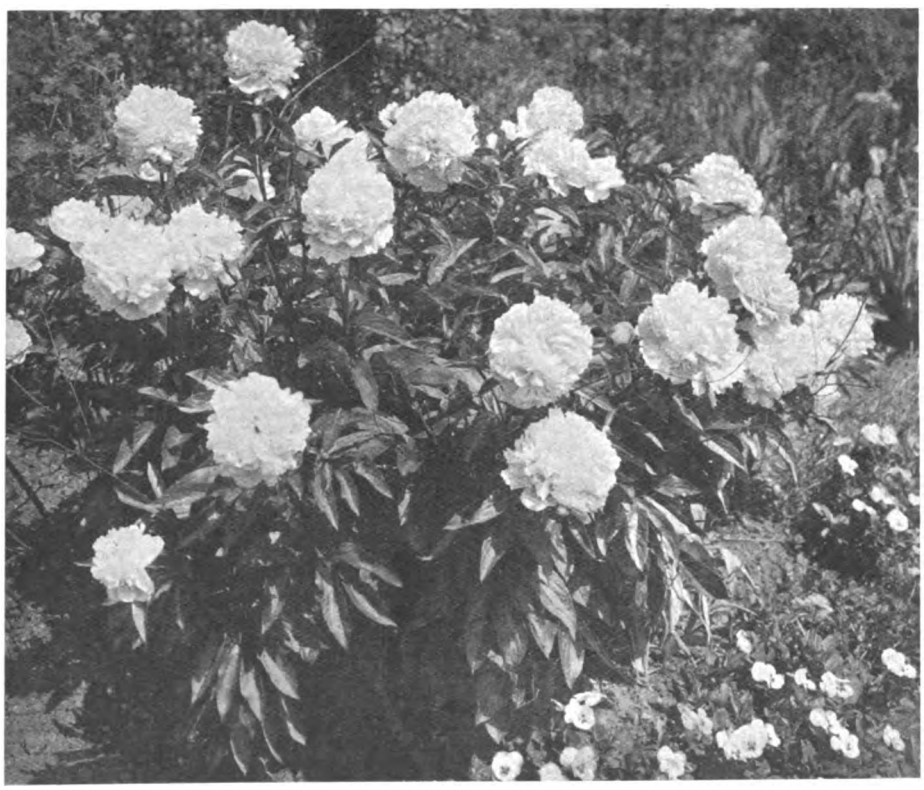
VICTOR HUGO, rich, deep blood-crimson. Fair-sized flowers carried well on stout stems.

KELWAY'S DIANA, a beautifully shaped flower. The colour is a delightful pink flaked with rose.

WILD ROSE, white, speckled all over with pink; unique, and most charming and delicate.

QUEEN ALEXANDRA, a most lovely flower of absolute purity of colouring; like an open water lily. Faultless white petals of perfect form and great size, with a golden heart, beautiful foliage. Early flowering.

LETITIA, beautiful bright rose, lively and effective.



THE GLEAMING WHITE BLOOMS OF KELWAY'S GLORIOUS.

EASTERN BROCADE, white flushed with pink, a "single" flower, rather cactus in shape.

DOUBLE VARIETIES.

MRS. JAMES KELWAY, the finest new double peony, extremely tall and robust. A tinted creamy white and very lovely.

KELWAY'S GLORIOUS, the most wonderful new peony sent out for many years; gleaming white, very full with rosy streaks on the outsides of the guard petals. Very sweetly scented. This variety is rated *second* in the world's list of peonies compiled by the American Peony Society.

Digitized by Google

SIR HENRY STONE, rose guard petals, short centre petals tipped and edged with gold. Very free flowering.

LADY ALEXANDRA DUFF, lovely French white—that is to say, not a snow white, although when fully open it is quite white—in the young stage tinted with a very fresh delicate pale shade of what is commonly called blush or palest pink. The back of the flower near the stem is flushed with pink. Tall and robust. Very scarce. One of the grandest varieties ever raised. First-class certificate, R.B.S.

LADY GWENDOLIN CECIL, delicate lavender flesh; a beautiful flower; very late flowering. First-class certificate, R.B.S.

DR. BONAVIA, of a very lively pink colour, paling at the edge of the petals; large flowers, showing golden anthers among the petals. Very sweetly scented.

WAR, large flowers of a dazzling crimson-scarlet, showing golden stamens in the centre. A beautiful variety.

LORD AVEBURY, a magnificent crimson-maroon. Nicely shaped flower held well above the foliage.

LADY CURZON, white guard petals with a bunch of cream-coloured petals in the centre, a faint blush tinge pervading the whole flower. Early flowering, very large and sweetly perfumed. Award of merit, R.H.S.

KELWAY'S DAVID, a most beautiful coral pink. Flowers very large and handsome, and produced well into July. This variety is quite an acquisition.

MRS. LUTWYCHE, pale pink and cream, grand, scented.

PRESIDENT POINCARE, splendid rich pure ruby crimson. A fine dark colour and spice-scented. Well formed incurved flower; semi-double.

NOTES OF THE WEEK

TAMARISK.

THERE seems to be a common impression that the tamarisk (Tamarix gallica) is only suitable for growing along the coast. As a matter of fact, this graceful shrub, with its feathery growth and clouds of pink flowers, may be grown successfully inland. Although the tamarisk grows best on a light sandy soil it will thrive quite well in almost any conditions. One advantage of the tamarisk is its quick growth, and quite small plants will, in a year or two, attain the height of 8ft. to 10ft. The tamarisk is easily propagated by means of cuttings of ripened shoots placed in sand and protected by a bell glass. A few bushes look extremely well mixed with other shrubs, on account of the distinctive growth of the plant. As well, the tamarisk makes a most excellent hedge plant. Strong young plants inserted about 12ins. apart will form a thick hedge almost more quickly than anything else. The shrub bears the constant clipping well and it develops an extremely dense growth. The tamarisk casts its small leaves in the winter, but these are retained until very late in the fall. Some while before the leaves drop they turn a bright orange yellow shade which makes the shrub most attractive in the autumn. By removing side shoots small trees of tamarisks are secured, and these make interesting specimens for the upper parts of a rock garden. —S. LEONARD BASTIN.

OMPHALODES CAPPADOCICA.

NO one who has a woodland garden can afford to overlook the subject of this note when making out their autumn lists. In general garden merit, which includes ease of culture and vigour, it is the best of its genus, flourishing with the freedom of O. verna and rivalling the excellent but fastidious Luciliæ in the large size and dainty elegance of its lovely porcelain blue flowers. In any freely drained, decent loam which does not get too dry, O. cappadocica will eventually spread over a wide area, its ample oval-pointed leaves making a dense carpet of pale green which easily holds its own against weeds. The airy sprays of blossom, rising to some 8ins. above this, are yielded in extraordinary abundance from early spring well into summer, and, as often as not, we get a secondary display in autumn.

O. cappadocica seeds with that moderation that marks its natural progress by offsets, and the seedlings are invariably true, unless you happen to get a hybrid, when the plant's indiscretion is quickly forgotten in the interest that invests the "little stranger." One such incident has occurred here, and, unless I am much mistaken, the lusty bantling which has arrived is a hybrid between the Cappadocian and O. nitida. At any rate, while it suggests a compromise between the two, its flowers are fully as large as those of cappadocica, and rather a deeper blue, yet it retains the narrower, glossier leaf and the single, non-spreading tuft of the other species. O. Luciliæ has had no hand in this business (the slugs have seen to that), and there is nothing in the seedling even to hint at a relationship with verna.—A. T. J.

PERPETUAL MALMAISON CARNATIONS.

MANY growers have, for various reasons, discarded the malmaison carnation, but they should not overlook the comparatively new type which, for want of a better description,

PERPETUAL MALMAISON JESSIE ALLWOOD

we may class as a hybrid between the old malmaison types and the perpetual-flowering. Some varieties of these are almost as free as their perpetual sisters; the flowers are, in general appearance, of the malmaison type, but the point to emphasise is that one can get good blooms almost at any time.

Hugh Low is a beautiful pink of great size and one of the best, but the older Minerva is still well worth growing. Miracle is a decided acquisition of much the same colour, whose flowers are larger than any of the others we grow. Boadicea is noted for the freedom with which it flowers, truly a dependable variety where demands may be frequent and large. Mrs. Myles Kennedy is a new colour, a deep salmon, very effective, delightfully and fully scented. The Hon. Charlotte Knollys is the deepest red we have, the flowers being borne on fine stems. Jessie Allwood must be included on account of its colour, yellow. Mrs. Cott is undoubtedly the most useful white and Lady Nunburnholme a desirable apricot.—HUGH AITKEN.

NOTES FROM NEW JERSEY.

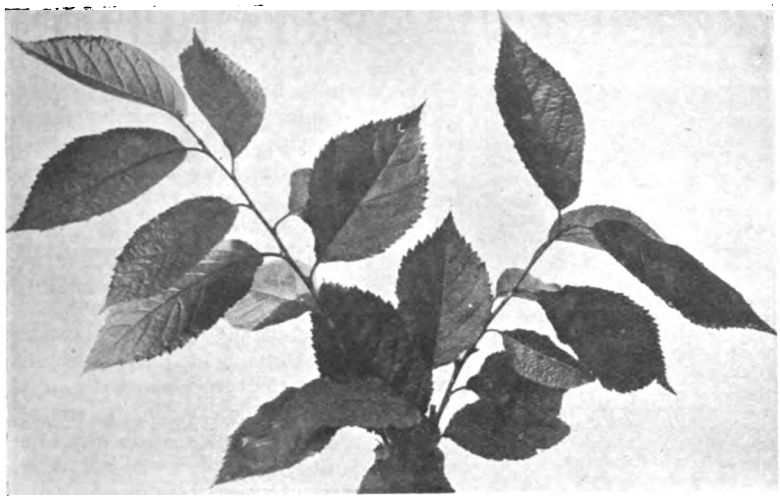
RESPECTING the use of teazles for decorative work, as suggested in THE GARDEN of October 10th, I may mention that here in the United States the florists are making a tremendous use of these odd flower heads, also dock flowers, lotus pods, bulrushes and all kinds of weeds and grasses that will hold up after drying. Numerous firms are specialising in the preparation and mounting of these items, and also pine cones. By clever dyeing and the use of metallic and other paints, these wildings are most gorgeously coloured, and made up for the most part into wreaths and other designs, also table centre-pieces for Christmas use, one or more candles being embodied in the latter.

Touching upon the question of colour charts, may I ask why Ridgway's Colour Chart is not mentioned? This, to our way of thinking, is the only colour chart of any value. It contains well over 1,100 colours; these are not prepared by printing, but are actually hand work. It is generally recognised that colour charts prepared by printing cannot be perfect, because the impressions by machine are always variable. For this reason the French work is not considered worth the price asked. One printing concern doing much colour work has informed me that no printing can be depended upon, and they therefore always recommend the Ridgway chart, which is a large book costing 12dols. By its use one can get an understanding of over 4,000 shades. Many industries use it, although, as your readers probably know, the textile industries have a system of numbers whereby manufacturers the world over can select the right shade without a pattern. One of our gladiolus growers here follows the textile system in his descriptions.

Regarding the wintering of corms and tubers, as discussed on page 574, I cannot agree that it is injurious to lift and cut off the tops of gladioli while green. Over here, scores of thousands of gladioli are grown; at least two firms grow 200 acres, while 10 to 20 acres are common, and all of them start lifting in October, cutting off the tops within 2ins. of the corms; they would never get through harvesting before winter set in if they attempted to keep the tops on. One of the oldest growers, Leonard Joerg, who has been in the game forty or more years, having formerly been with John Lewis Childs, told me that cutting off the tops while green has no injurious effect if the growth is complete, and three years' personal experience proves it to be so.

On the other hand, I do not cut down and dig my dahlias until a really hard frost has cut down the stems; this season we had

Digitized by Google



THE FOLIAGE OF PRUNUS PSEUDO-CERASUS, SHOWING COARSE SERRATION.

a frost on October 10th, earlier than usual, which was just severe enough to destroy all flowers and foliage without damaging the stems to any extent. By leaving the plants until thoroughly cut down, the roots will make up considerably, although there is practically no foliage. The same applies to cannas. Montbretias in this section, by the way, have to be treated rather like gladioli, as they are not sufficiently hardy to be a certainty; I lift the bulbs around the end of October and store in peat moss.—T. A. W., *New Jersey, U.S.A.*

ASTER NOVI BELGII VAR. CLIMAX.

THERE are now many choice coloured Michaelmas daisies, and even semi-double flowered varieties have been added further to swell the already numerous lists of good varieties. One kind, however, which I think worthy of special note is that named Climax, one of the Novi Belgii section. It is not so many years since it was classed among the new varieties, and stated to be "the largest-flowered variety in cultivation," but there are others, such as Mother of Pearl, with lilac-pink flowers 2ins. across, in fact this variety would almost pass for a single chrysanthemum. Then King George is another kind with very large flowers.

Two years ago we received a small plant of Aster Climax, and early in November of last year a few of the growths were taken from the plant and inserted round the sides of a pot containing medium fine sandy soil, and the pot set in a close frame. By February the cuttings were splendidly rooted, and later planted out in the open border. The borders had been well trenched and manured some time previous to the planting; it is not surprising, therefore, that the plants grew apace and reached the height of 5ft., being healthy and vigorous, and at the date of writing, November 7th, they are adorned with numerous large bluish-heliotrope flowers with yellow centres. The foliage, too, is clean and glossy green, furnishing the stems almost to the ground level. Aster Climax should be included in all collections, as it is "the finest single aster." The colour is charming, and to me certainly more so after the flowers have been expanded for two or three days.—DAVID ARMSTRONG.

PRUNUS PSEUDO-CERASUS, LINDL.

ITS habit of flowering in the open during the early part of February, makes this a very useful plant. It is also a very interesting one, because it is so little known; but this is not to be wondered at, for up to the last few years it was not thought to be in cultivation. Although I believe it has recently been put on the market from material taken from the specimen here, I think I am quite safe in saying the plant here is unique, in being the only specimen of any size in the country. The inflorescences, which are in clusters of from six to twelve, consist of short racemes, or corymbs of from five to eight flowers, which are ruddy red in the bud stage, being pale pink when open, the two together giving the shrub a very telling effect. The bracts are small and jagged, those of the upper flowers being smaller. The stalk and calyces are of a ruddy red, the stalks hairy, and the calyx tube glandular. The petals, which are two-fifths of an inch long and a quarter of an inch wide, have a double notch at the tip, with always one tooth and sometimes more than one between the two notches.

This species is sometimes confused with Prunus serrulata, many of the double forms of that species being referred to this interesting and distinct cherry, but there are wide differences. P. Pseudo-cerasus always flowers in February. P. serrulata and its varieties in April and May. In P. Pseudo-cerasus the leaves and flower stalks are hairy, while in P. serrulata they are glabrous. The leaf blades, which, as I have already said, are hairy, are more or less obovate, rather broadly acuminate, the edge being coarsely doubly serrate, whereas the leaf blade of P. serrulata is ovate, glabrous on both sides, with a long, tapering point, the serration much finer and not double, the leaf stalk being from 1in. to 1½ins. in length and glabrous, while the leaf stalks of P. Pseudo-cerasus are about ½in. long and hairy. The leaves of P. Pseudo-cerasus remain on the tree quite late in the autumn, being quite green, when those of P. serrulata are yellow and falling.

Flowering as I have already said, early in February, makes it a very valuable ornamental shrub; of course, there is always the risk of the flowers being damaged by frost, but even then should the frost be not too severe and long, the later buds will sometimes open and give a good display.

The specimen here is 15ft. high and 21ft. through, and nothing can be more beautiful during a spell of mild weather in February than this plant covered with its masses of flowers and buds. Even if the flowers are destroyed several years in succession, it is well worth growing for the one season it does escape, while it might be quite a useful plant for pot work for decorating the conservatory.

It is a native of China and appears to have been introduced into this country about 1819. It was described by Lindley in "The Transactions of the Horticultural Society," Vol. VI, in 1826, while either this or a very similar plant was figured in the "Botanical Register," tab. 800, under the name of P. paniculata, in 1824.—F. G. PRESTON, *Botanic Garden, Cambridge.*

THE LATE MR. W. R. DYKES: AN APPRECIATION

IT is a sad task to have to announce the death of Mr. William Rickatson Dykes, the secretary of the Royal Horticultural Society, who died on Tuesday, December 1st, as the result of a motor accident which occurred near Woking on Friday, November 27th.

Mr. Dykes was born in 1877, and was educated at the City of London School, at Wadham College, Oxford, and at the Sorbonne in Paris. He was a master at Charterhouse for sixteen years. In 1920 he was appointed secretary of the Royal Horticultural Society on the retirement of the Rev. W. Wilks.

Although many will remember him as the foremost authority of his day on the genus iris, yet to most horticulturists his memory will remain green as the energetic secretary of the premier horticultural society of the world. In this work his energies were unflagging. He took on the secretaryship at a time when post-war gardening had just started on its victorious career, for the popularity of gardening is increasing by leaps and bounds, and his labours had much to do with the extraordinary increase of membership in the R.H.S., which now stands at over 23,000.

THE LATE MR. W. R. DYKES, M.A., L.-ès-L., V.M.H.

His death is a sad loss to all who knew him. His post was no sinecure, and he performed all his hundred and one duties with a calm energy and a strength of purpose that has done more towards making the R.H.S. the great society it is than many people imagine. We on the staff of THE GARDEN had frequent occasion to ask his help and advice, and never asked in vain. He had an extraordinary capacity for detail in anything in which he was interested, as noticeable in his work at Vincent Square as in his investigations into irises, tulips and crocus. Unlike many investigators, he was both scientific and practical, and he knew his plants not only as herbarium specimens, but also as denizens of the garden.

All readers of THE GARDEN will join with us in expressing our sympathy with Mrs. Dykes over her sad loss. A memorial service, which was attended by many of his colleagues on the Council of the R.H.S. and many Fellows, was held on Friday last at St. Stephen's Church, Westminster.

With the popularity of gardening has grown up almost hand in hand that of the iris, and it is due to the pioneers like Sir Michael Foster and the late Mr. Dykes that the genus has attained its present high standing. His labours have not been in vain, and his name will for ever be closely associated with the *fleur de luce* and the many fine forms and varieties which he has presented to the horticultural world.

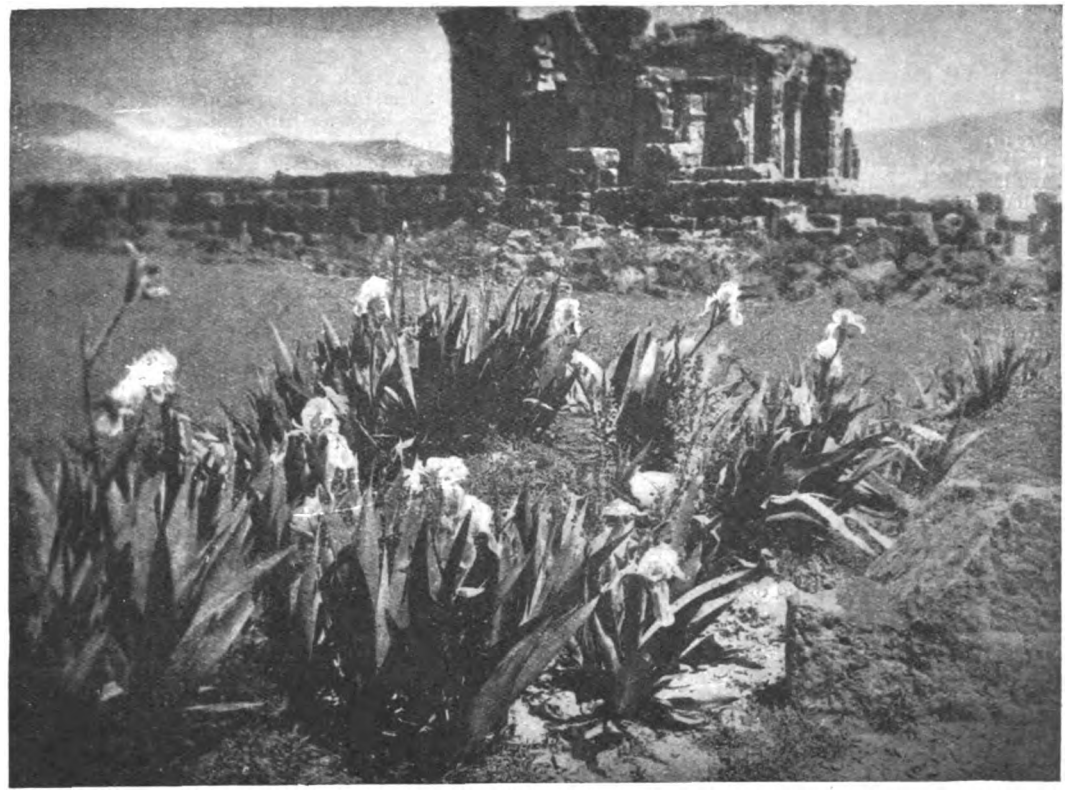
In all sections of the genus the influence of his hand is to be found. He worked hard for some considerable time at the Apogon irises, crossing them not only with one another, but also with the bearded kinds. Among the pallida varieties he effected great improvements, and the one which is illustrated here was one of his brightest and best seedlings among the pink pallida varieties. It is a tall and shapely variety with just that tinge of delicate violet pink which gives to it a considerable charm. It is, indeed, a gift of which the iris world may well be proud. Sapphire is another of his introductions, and is so well known among iris lovers that its description would seem superfluous. Another exceedingly fine variety which he raised in 1921 is Ariadne. A charming little pallida hybrid which we also owe to his labours is Aquamarine, whose distinct blue tones are so often seen in happy combination with his Sapphire.

As an indication of the extent and period of his labours we would draw attention to the variety Goldcrest, which he raised as far back as 1914. The flowers of a bright violet blue with a golden beard have captured the hearts of all lovers of flowers. In the same year he presented the iris world with yet another fascinating variety in Richard II, which still remains one of our most prolific kinds. After the war years his additions to the genus became numerous, not only in the production of fine garden varieties, but also in the addition of not a few species, including the aristocratic Iris Hoogeana from Turkestan. His extensive list of introductions to the iris family is, indeed, an imposing one, and the result of years of patient study and research.

THE TALL AND HANDSOME APHRODITE. One of Mr. Dykes' notable introductions to the Iris World.

His work on the genus did not finish with the growing of the plants. He has left to the gardening world contributions to literature which, like many of his varieties, will remain as the standard works for a number of years. His first volume on irises was a small one published in the Present-Day Gardening Series in 1911. This was followed by his great work in the form of an admirable scientific monograph on "The Genus Iris," which is now recognised as the standard work on the family throughout the world. Last year "A Handbook

Digitized by Google



of Garden Irises" came from his pen, and already the value of this volume has been widely recognised by all gardeners, filled as it is with many practical hints on the culture of the iris, the outcome of his many years' experience with the flower. From the foregoing it might appear that his efforts and attentions were all centred on the iris, but this was not so. His outlook was wide and his interests catholic. In recent years he devoted much of his time to the genera tulip and crocus, and had he lived there is no doubt that the gardening world would have benefited greatly by his painstaking research and wide knowledge. In other branches of horticulture he was equally versatile, combining to a marked degree theoretical and scientific knowledge with a rare intuition of the requirements of the practical man.

For his untiring efforts in all branches of gardening, and more especially to those which have transformed the iris from the mere "flag" of a generation ago into a flower beloved of all gardeners, all horticulturists owe to him a debt of gratitude that can never be repaid.

WE GLIDED WINDING UNDER RANKS OF IRIS AND THE GOLDEN REED.

DECEMBER AT VINCENT SQUARE

THAT the season has almost reached its ebb was very much apparent on the occasion of the second last Fortnightly Meeting of this year of the Royal Horticultural Society at Vincent Square on December 1st last. The exhibits were decidedly miscellaneous in character, the exhibits of garden sundries being a prominent feature. The floral groups of chrysanthemums, carnations, begonias and orchids, which were all good considering the time of year and the hard weather conditions, lent a touch of colour to the Hall, together with the paintings and drawings of the many artists who were exhibiting. The various stands devoted to sundries merit the attention of all who attend the shows at this period of the year. Much useful information may be garnered which will stand one in good stead in the coming months.

Two good chrysanthemum exhibits were staged, one by Messrs. Keith Luxford and Co. and the other by Mr. A. G. Vinten. In both cases the single varieties were particularly fine and well grown. The stand of Messrs. Keith Luxford was large and in a good position. The back was decorated with bold pillars of Japanese varieties, such as Julia, a fine rosy bronze sport of Mrs. B. Carpenter; Thomas W. Pockett, with large well formed flowers of silvery pink; and the amber-coloured variety, Majestic. Some good new singles, such as Envy, Everbright and Criterion, were also noted. The strange coloured Mme. E. Roger, with its greenish shaded florets, stood out from among the reds and yellows; and Caleb Cox was a golden bronze anemone-centred single. The fine chrysanthemums shown by Mr. A. G. Vinten were not seen to the best advantage, owing to the poor position which his stand occupied. Balcombe Beauty, a beautiful golden yellow sport of December Bronze, was most attractive; and Ada Brooker was a striking incurved variety. Miss Joyce Moore, one of the largest and best crimson singles; Nona, a pure white borne on stiff stems; Mrs. W. E. Catlow, a good yellow single; Mrs. A. Robertson, a clear pink; and Challenger, a chestnut red single with a gold disc round the eye, were some of the best. Messrs. Sutton and Sons had an interesting exhibit, which consisted of seedling chrysanthemums in a variety of colours. The seeds of these were sown during February last and were grown on without staking, stopping or disbudding. Some of the colours were excellent, particularly the gold and bronze shades.

Several fine groups of carnations were staged. Messrs. Stuart Low exhibited a large collection of perfect blooms. Lady Hindlip, Winsome, Sir Philip Sassoon and Sheila Greer were outstanding. Two novelties were Lady Nall-Cain and Sybil. An attractive new variety named Nero was shown by Mr. C. Engelmann. Betty Loo, Red Peerless, Red Laddie, Saffron and Improved Ward, shown by this raiser, were also in good form. Messrs. Allwood Brothers had a representative collection of perpetuals, including such varieties as Laddie, Chintz, Master Michael Stoop, Wivelsfield Claret and Topsy.

Fruit, in the form of apples, was shown by Messrs. G. Bunyard and Messrs. Laxton Brothers. Mr. G. Whitelegg showed shrubs and alpines; Mr. John Klinkert, topiary trees; and Messrs. L. R. Russell and Co. staged a large and imposing group of foliage plants of all kinds. Hardy plants were shown by the Misses K. and E. Hopkins; and St. Brigid anemones by Messrs. Reamsbottom and Co. Good orchid exhibits were staged by a number of firms, including Messrs. Black and Flory, Cowan, H. B. Brand, H. Dixon, J. Cypher, H. T. Pitt, Sander and Co..

In conjunction with the above meeting of the R.H.S., the British Carnation Society held its winter show. Although it was quite a small show, so far as the competitive classes were concerned, the quality of the blooms was particularly good. The enthusiasts were especially interested in the splendid seedlings which have been raised by Messrs. W. E. Wallace and Son in their well known nurseries. Not only were there many blooms of superb quality, but this was enhanced by the artistic method of arrangement. We were especially impressed by The Favourite, a beautiful soft pink variety; Enid, a rounded rich crimson bloom; Our Prince, a glowing scarlet; and Spectrum, a large flower with regularly fimbriated margins and of bright crimson colour.

In the competitive classes the principal prizes were won by Mr. Jas. Humphrey, who showed magnificent flowers. Sir Chas. Nall-Cain, Bt., won several prizes with nearly as good blooms, and Mr. R. Chetwynd-Stapleton also staged very good blooms.

Judging from the show, the best varieties for winter blooming are Crystal White and White Pearl; Betty Low and Headland's Beauty, bright rose pink; Laddie and Lady Northcliffe, salmon pink; Tarzan and Edward Allwood, scarlet; Topsy, crimson; and Violet Mond, bright purple. The best fancy carnation was Benora.

Unfortunately there was only one collection of carnations in the competitive and although Mr. Jas. Humphrey had an excellent exhibit, one would have liked to have seen more shown in this valuable manner. The varieties so tastefully displayed were chiefly Spectrum, of vivid colour; Lord Lambourne, which the raisers are justified in describing as a gorgeous scarlet; Mrs. Hamilton Fellows, deep purple; and Crystal White. Although there was no yellow variety in these competitive classes elsewhere, the huge vases of Saffron indicated that it cannot be very difficult to produce blooms of this rich yellow during the winter months.

NEW AND RARE PLANTS.

ASPARAGUS PLUMOSUS BOUNDII.—This highly decorative greenhouse asparagus is a more compact variety of the well known A. plumosus nanus, and has a distinctly fern-like appearance. The plants on view indicated a prolific habit and it should be a valuable variety, both as a pot plant and for supplying cut sprays for decorative purposes. Award of merit. Shown by Messrs. Bound and Son.

PAVETTA ABYSSINICA.—A quite appropriate description would be short-stemmed corymbs of waxy white ixora-like flowers set on the side branches of a viburnum. It is a hothouse shrub which at Kew has become nearly 20ft. high and, as the specific name indicates, is a native of Abyssinia. The filaments of the starry flowers are unusual, but there does not seem to be any perfume. Award of merit. Shown by the Director, Royal Gardens, Kew.

CARNATION LADY HINDLIP.—This is a large and handsome fancy variety. The well formed blooms are regularly lined with deep rose on white ground and are pleasantly scented. Award of merit of the British Carnation Society. Shown by Messrs. Stuart Low and Co.

ORCHIDS.

AWARDS OF MERIT.

ODONTOGLOSSUM ROBIN HOOD (Mars illustrissimum).—This hybrid is noteworthy on account of its intense crimson-red colour, which is solidly displayed on all the segments, with the exception of a narrow white border line. The spike bore six flowers of medium size. Shown by Mr. Robert Gerrish, Milford Manor, Salisbury.

VUYLSTEKEARA LUTETIA (Vuylstekeara Brewii × Odontoglossum luridum).—A promising novelty with a couple of flowers in which the labellum is developed as in Miltonia vexillaria, being large, and of blood red colour at the base, purplish on the apical half, the middle area rose-tinted and much spotted with reddish crimson. The sepals and petals are flushed with crimson red. The generic name Vuylstekeara denotes a hybrid combining the genera cochlioda, odontoglossum and miltonia. Shown by Messrs. Charlesworth and Co., Haywards Heath, Sussex.

CYPRIPEDIUM LOCARNO (Albert Fisher × Christopher var. Grand Duke Nicholas).—A large flower composed of broadly developed segments, the dorsal sepal having a greenish base, marked with light purplish spotting which extends over the white upper portion. The ventral sepal is almost of equal size and similarly marked. The petals yellowish, stained with brown, the labellum broadly developed and of dark brown colour. Shown by Messrs. Black and Flory, Slough.

NEW CHRYSANTHEMUMS.

The four following varieties received the first-class certificate of the National Chrysanthemum Society on November 30th, and the award of merit of the Royal Horticultural Society on December 1st.

BELLE CHINOISE.—A very beautiful exhibition Japanese bloom of perfect form. The narrow drooping florets are of bright yellow colour. Shown by Messrs. Keith Luxford and Co.

DELICATA.—A medium-sized Japanese variety of reflexing type. The colour is a delicate mauve which is rather paler in the centre of the bloom. Shown by Mr. H. Shoesmith, Junr.

PINK PRIZE.—This is a small Japanese variety with broad florets of deep pink colour. Shown by Mr. H. W. Thorpe.

RUBY RAY.—A most brilliantly coloured small single. The florets are broad and substantial and of rich velvety crimson colour. Shown by Mr. H. W. Thorpe.

The two following received the N.C.S. first-class certificate.

JEWEL.—A decorative variety of good size and made up of narrow, pointed reflexing florets. The light chestnut colour and golden reverse make it an especially valuable variety for decorative purposes. Shown by Mr. H. Shoesmith, Junr.

JOHN LINGWOOD.—A beautifully formed single of rather more than medium size. It has broad, blunt florets of rich yellow colour. Shown by Mr. E. J. Henderson.

ENDIVE.

MAY not one of the reasons why so few grow endive be attributed to prejudice against a most useful salad plant? I cannot conceive of any other explanation. Outside large establishments, scarcely one in ten attempts its culture, yet it needs practically identical treatment to that of lettuce with additional time for blanching. Presenting a small basket of lettuce to a friend last summer, I included a couple of green curled endive for the salad bowl with other things. It was pronounced as "very nice," though it was the first time it had been used. Lettuce is, of course, the base of a really good salad, and endive cannot well be left out.—W. F.

CYMBIDIUMS FOR AMATEURS

BY GURNEY WILSON.

IF we enquire why so much interest has been taken during recent years in the cymbidium genus, it will be found that, with the possible exception of cypripediums, no plants are more easily cultivated or produce a finer display of bloom.

Concerning the various species from which the present-day hybrid cymbidiums have been produced, there are a few which stand out prominently in the records. Cymbidium eburneum may be taken first. Its owes its specific name to the ivory white nature of its elegant flowers, a character that has been perpetuated in most beautiful style. While it is true that this species rarely produces more than two or three flowers on each spike, this number is greatly increased in nearly all of its hybrids. Another cymbidium that was very popular in the older collections is C. Lowianum, with its arching spike of about twenty flowers, greenish yellow, and with a prominent V-shaped blotch of red-crimson on the lip. The hybrid known as C. eburneo-Lowianum, combining the principal characters of the two above-mentioned species, enjoyed much popularity for a considerable period, but at last had to give place to the newer race of hybrids now to be described.

The reintroduction of Cymbidium insigne about twenty-five years ago afforded the means of producing one of the most beautiful series of hybrids that has as yet been seen in any genus of the orchid family. The free-growing habit of this species and its tall spikes of rose-tinted flowers effected marvellous changes in the type of cymbidium formerly cultivated. The first flowering of C. Alexanderi (insigne × eburneo-Lowianum) was an immediate success, for its elegantly formed flowers of varying rose tints provided a welcome change from the somewhat sombre colours of such species as C. Lowianum, C. grandiflorum and C. Tracyanum. One cannot attempt to name even a proportion of the numerous hybrids that have recently been produced through the use of C. insigne, either as a seed-bearer or as the pollen parent. Even plants raised from the same seed-pod show considerable variation one from another, while the range of coloration which can be obtained by selection may be said to commence with pure white, passing through shades of cream and yellow to even golden yellow, and also through blush-tinted flowers to those of the deepest rose. In addition, there are now many kinds whose flowers are of bronze tints as elegant as they are difficult to describe. To put the whole matter as briefly as possible: C. insigne has produced a greater number of beautiful hybrids than any other species of the genus. Hence we understand why in many gardens the whole area of a greenhouse is given over to the cultivation of cymbidiums. The principal reason why cymbidiums are eminently suitable for cultivation by amateurs is that they belong to the cool-house section of orchids, or, in other words, the house in which they are contained should not have a lower winter temperature than 45°. On frosty nights a slightly lower figure will probably occur, but it will do no harm so long as it does not continue for any prolonged period. But if we desire to obtain the finest results, something more than merely keeping the plants alive must be done. The warmth of the sun is just as important to the well-being of cymbidiums as to the majority of other orchids, and on that account the early morning and afternoon sunshine is very beneficial, but shading must be afforded on all occasions when there is a danger of the foliage being scorched. No precise directions can be given, for the conditions vary so much with respect to the position of the greenhouse and the locality. Vigorous growth and satisfactory flower-spikes only result from suitable atmospheric conditions, and it should be the aim of the cultivator to produce them as frequently as the outside weather conditions permit. If there is one thing that cymbidiums seem to dislike, it is being shut up in a stuffy atmosphere. A light, buoyant atmosphere kept moist by occasional syringing of the path and under the staging should be within the means of every amateur to maintain. The plants themselves should never be dried off, only during the few weeks following the flowering season will they need slightly less water, for it is then that the growth is less active. On the other hand, the plants must not be overwatered, or the compost will soon become a sodden mass and lead to the decay of the roots. During the growing season light spraying of the foliage on all bright mornings is beneficial. This will prove especially useful during the summer months in keeping down thrip attacks, but it will generally be found that periodical spraying with an insecticide is necessary.

Cymbidiums are generally treated as of terrestrial habit, and this means that they will thrive well in a mixture of turfy loam rendered fibrous by the addition of about one-fifth of peat and a similar proportion of sphagnum moss. Some cultivators advise the inclusion of half-decayed leaves. In order to produce a porous compost, it is as well to include some crushed crocks or coarse sand. The best time to re-pot cymbidiums is soon after their flowering season. The majority will need attention annually, but it is not advisable to remove all the old compost from the larger specimens, and some of these may go for much longer periods without any harm. While care is necessary to ensure that the plants are not starved by being kept in too small a size of pot, it is equally important that they should not be surrounded by more compost than they can make use of. There should be ample room for the new growth to form itself into a bulb of satisfacory size. On the completion of this growth the pot should be fairly well filled with roots, for experience shows that pot-bound plants generally yield the finest flower-spikes.

CYMBIDIUM MIRANDA VAR. BRONZE BEAUTY.

CORRESPONDENCE

THE BOMAREAS.

SIR,—In his interesting note on the new hybrid bomareas raised at Glasgow, Mr. E. H. Banks rightly states that these beautiful climbers are not sufficiently known. He is, however, mistaken in saying that only five species are now in cultivation. Besides those mentioned should be included B. multiflora from Colombia, a beautifully spotted red and yellow species, and B. Wercklei, a native of Costa Rica with bright red flowers. These two species succeed admirably outdoors in West Somerset, where they make annual growths at least 12ft. in length, each terminated by a large cluster of very striking flowers. They appreciate the support and shelter of other plants through which they climb. In a severe winter all the shoots are liable to be killed to ground level, but in a mild season (such as 1924–25) the foliage remains undamaged and flowers open as early as April. In fact, B. multiflora has flowered steadily here from the middle of April up to the end of November this year. Moreover, it is carrying quantities of fruit containing ripe seed. B. Wercklei has also ripened seeds in a neighbour's garden and young plants have been raised from these. I have little doubt that other species of bomarea would prove equally successful in favoured districts. In addition to the species mentioned above and by Mr. Banks, the Kew Hand List of Tender Monocotyledons (1915) mentions B. frondea (Colombia), B. Salsilla (Chile), B. Shuttleworthii and B. Williamsiæ (both from Colombia), as well as a hybrid B. Caldasiana ×hirtella. B. oculata is sometimes offered by nurserymen, but this is a synonym of B. Salsilla.—N. G. HADDEN, *Porlock*.

WINTER THUNDERSTORMS.

SIR,—In December last an appeal was made through the Press for information regarding thunderstorms occurring in the British Isles between January 1st and March 31st, 1925. I should like to thank the large number of observers who sent reports. The number of days on which thunder or lightning was reported was as follows:

1925.	*Eng. & Wales.*	*Scotl'd.*	*Irel'd.*	*Brit. Isles.*
January ..	10	12	10	17
February .	20	10	8	23
March ..	16	5	4	17
T'tl (3 mos.)	46	27	22	57

There was a large area in Wales and another in the northern counties of England which were free from storms: also a belt stretching from east Yorkshire to south-east Wiltshire. The stormiest areas in England were mainly on or near the south coast: the southern parts of Sussex and Surrey were very pronounced. In Scotland the storms occurred mainly in the central portion of the west coast.

The investigation will be continued during the coming winter.—S. MORRIS BOWER, *Langley Terrace, Oakes, Huddersfield.*

MOVING SHRUBS.

SIR,—Most shrub lovers find it very hard to prune back severely a shrub which has been the glory of the garden for weeks, but in their hearts they know it must be done and would like to be backed by experienced fellow shrub lovers. There is another point which would be interesting to know, that is, which shrubs bear moving well and which do not.

Mr. Osgood McKenzie, whose knowledge of shrubs was hard to beat, and who spent a week here with me the year before he died, said, "Don't forget that rhododendrons love carriage exercise; you need have no fear of moving any of them, no matter what the size," and recently I read your Editorial on "The Disturbance of Plants," where you quote Sir Isaac Bayley Balfour as saying, "theoretically the best way to grow a rhododendron is to sow the seed in the exact place where you hope to see the plant reach maturity"! May I suggest that readers of THE GARDEN be asked to write their own experiences, successful *and otherwise*, of individual shrubs. As this garden was, when we bought it in 1910, a rocky island in Bantry Bay, where no cultivation beyond two or three small patches of potatoes had ever been carried out, and where to make gardens possible rocks had to be blasted in every direction to enlarge the existing small earth pockets, shrubs have had to be moved over and over again, and gardening has all been experimental but intensely interesting. Shelters everywhere had to be planted and the ground prodded to find if it was possible to plant, and in the process of waiting for the protection to grow up many precious plants were, of course lost; but that is the lot of the gardener and the way experience is bought and, incidentally, interest increased.

Speaking of shelter plantations, we found Cupressus macrocarpa, Pinus Laricio and P. insignis the best shelter trees. Before we realised the necessity of topping the insignis we lost several, which in ten years had grown to be trees of 40ft. in height and of very large girth. All the trees planted by us were 3ft. and under. Cupressus macrocarpa planted in 1913 are now over 50ft. and make magnificent shelter. Pinus Laricio we found stood the wind much better than P. sylvestris (I prefer the simple name of Scots pine; it seems to suit it!), though neither of them, needless to say, have achieved anything like the size of the macrocarpa or insignis. The Douglas fir has reached 30ft. in the time, but only where it has had good shelter. They lose their leaders and get bare on the windward side. It seems to me it is never too late to start planting, though few can hope to see their beloved trees reach their zenith.—MRS. ANNAN BRYCE, *Glengarriff, Co. Cork.*

THE HEATH GARDEN AT GLENGARRIFF.

SAGE, SALVIA OFFICINALIS.

SIR,—With reference to W. Oswald Waits' enquiry, "Red Sage," the following is from Loudon's Encyclopædia, attributed to Abercrombie: "The Red is the principal sort in culinary use, having the most agreeable and fullest flavour. The green is next in estimation with the cook. But the small leaved is generally preferred to those to eat as a raw herb, and for decoctions, while the broad-leaved balsamic species is the most efficacious in a medical way, and is also a Tea herb, however any of the sorts may be occasionally used for those alternate purposes."—E. YOUNG, *Herts.*

SIR,—Another query arises concerning this plant out of the enquiry made by a correspondent on page 663 of THE GARDEN. Did the writer in the *Spectator* mean the red flowering sage or the sage bearing the reddish purple foliage of the garden variety or common sage? The latter is occasionally seen in old gardens, its foliage assuming the above colour—not always very pronounced—as the season advances. The suspicion of reddish tint noticeable in the foliage being enough, no doubt, to ensure the term red being loosely applied by folk of other days.

On the other hand, if it be a red-flowered variety which is wanted, Mr. Robinson in "The English Flower Garden," tells us there is a scarce French form of the wild sage (Salvia pratensis), bearing deep, pure red spikes, and one might hazard, if this variety is not obtainable from an English nurseryman, it could be got through the latter for anyone.

An old gardening dictionary I possess mentions a red sage with variegated leaves; and also one called red sage, but no reference is given whether the latter red means flowers or foliage. In Messrs. Heath and Heather's (of St. Albans) list of medicinal plants, red sage is recorded, so perhaps that firm could supply information, if not the plants.—C. TURNER, *Ampthill.*

LINUM MONOGYNUM.

SIR,—The description given of a white-flowered linum by Mr. T. Ashton Lofthouse exactly fits L. monogynum, and I know the late E. C. Buxton had several plants of that species from me. This flax is, as your correspondent suggests, a very beautiful one and I have found it to be absolutely hardy, long lived and not at all fastidious, doing in almost any soil in sun or part shade. The glaucous foliage is distinct and attractive even in winter, and the large, pure white flowers are yielded in an unbroken succession throughout the summer. L. monogynum, moreover, sets seed abundantly and this germinates in the open ground. It is a New Zealand species.—A. T. JOHNSON, *N. Wales.*

HABIT OF VIOLAS.

SIR,—I am pleased to reply to your correspondent who desires to know the names and descriptions of a few violas of close-growing, neat habit, for edging purposes.

Violas that are useful and suitable for bedding are not necessarily good for edging purposes. Their growth, though tufted in character, may be too robust, making tufts

Digitized by Google

that are somewhat too loosely formed to make a really satisfactory edging.

Some varieties have a very dwarf and close-growing habit, the plants forming cushions of growth only 3ins. or 4ins. in height, while others, though by no means straggling in growth, are not so short-jointed and consequently are not so neat growing.

Then there are the violettas or miniature violas. Practically all these are suitable for edging. There are not many distinct varieties in commerce yet, however. The species gracilis and cornuta and garden hybrids and varieties thereof are useful for edging, although the cornuta type are inclined to get somewhat leggy as the season advances.

The following varieties can be recommended for their compact and short-jointed growth :—

White.—Seagull, rayless pure white. Peace, creamy white tinted blush. Violetta, the original of the violetta type. Purity, a robust growing violetta.

Yellow.—Ardwell Gem, an old, well tried variety of creeping growth, golden yellow, lightly rayed. Redbraes Yellow, rayless golden yellow. Goldfinch, similar in all respects to Ardwell Gem, from which it is a sport, except that it is edged with lilac—a very useful sort.

Mauve and Blue.—Dunbryan, rayless, pale lilac mauve. W. H. Woodgate, lavender blue, a very effective colour. Newton Mauve, violet mauve. John Quarton, lavender mauve. Violetta Eileen, dark bluish mauve. Violetta Queen of the Year, china blue.

Purple.—J. B. Riding, an old variety purplish mauve, very compact. Councillor Waters, dark purplish blue. Dr. MacFarlane, purple and lavender bicolor.

Bronze.—Redbraes Bronze, mahogany brown. President, bronzy purple, grows tall as the season advances, however.

The nature of the soil in different localities and other conditions will, of course, cause some sorts to vary accordingly. The above list does not pretend to be in any way exhaustive, but comprises a few varieties that have been used and found suitable for the purpose mentioned.—HOWARD H. CRANE.

POLYANTHA POMPON ROSES.

SIR,—In THE GARDEN for October 17th there is an interesting article on "Polyantha Pompon Roses," by "White Lady." These roses are great favourites of mine, and while I quite agree with "White Lady's" remarks as to their general lack of scent, I cannot understand why she does not mention the dwarf polyantha Eugénie Lamesch in any way. I have had a bed of this charming polyantha for years, and it is of dwarf habit and a splendid and continuous flowerer. Its great charm is its scent, which is quite a strong one, and similar to that of violets. When the plants are in full bloom the air is filled with their fragrance at some distance from the bed.—M. L. B., *Ryton-on-Dunsmore.*

NERINES: A QUESTION TO GROWERS.

SIR,—I have been closely watching the pages of THE GARDEN during the past two months on the look-out for tidings of this season's flowering, but in vain. Even the Rev. Joseph Jacob, high priest at the nerine's glittering shrine, has failed to tell of his annual festival of blossom. So, to start the theme, from my own small personal experience I record the fact that my bulbs have behaved somewhat strangely this year.

As a rule, the bud spikes first appear, only a few blades surrounding the opened blooms, while the main display of foliage follows as the umbel withers. This season only about one-half of the flowering bulbs observed the wonted routine, and I duly deplored my failure in percentage of blooms. Subsequently the "grass" rose in strength and during the latter part of the present month, several weeks later than in former years, many welcome flower-spikes have been springing out of the almost full-grown foliage. These, be it noted, bid fair to carry much smaller heads of blossom than is the case when the flowers practically precede the leaf blades.

My object in writing is to ask expert growers of nerines whether their experience of the 1925 crop in any way corresponds with my own.—R. H., *Stratford-on-Avon.*

MICHAELMAS DAISY EDWIN BECKETT.

SIR,—May I say that since the article appeared in which I said I did not know who catalogued this remarkable Michaelmas daisy, I have found that it is listed by Messrs. J. Stormouth and Son, Kirkbride, Cumberland, and Mr. Charles Turner, The Royal Nurseries, Slough. In one list it appears under "ericoides" and in the other under "cordifolius." I should say from its general look that it is a cordifolius. Whatever it is, it is a real beauty.—JOSEPH JACOB.

SOME SWISS ALPINES.

SIR,—The letters and articles recently published in THE GARDEN by those who have enjoyed plant-hunting in the Alps have been of very great interest. Mr. Holdsworth in his letter (page 633) is quite correct in speaking of hybrids of Primula glutinosa × minima on the Passo delle Selle. When there on August 15th last I was fortunate enough to find P. × Floerkeana and P. × biflora. The plants had been long out of flower, but the rounded toothed leaves and mat forming habit were unmistakable. The hybrid × salisburgensis was only found on Colbricon—that is, if Farrer is right in saying that this hybrid only is found there, for the few plants seen differed very little in leaf from those found on the Selle Pass.

The mountain districts east and west of the Adige seem particularly rich in hybrid primulas. P. × discolor and a series of hybrids between P. spectabilis and P. minima were found in the west and what appears to be a hybrid between P. œnensis and P. glutinosa: but these plants are hard to determine—and also to find—when out of flower.

You have, Sir, asked in your pages for the experiences of those attempting to grow the more difficult plants. Whether the large amount of sun we have enjoyed this season is responsible I cannot say, but for the first time since the plants were brought here in 1922, Androsace glacialis has flowered in character—over thirty flowers on a 2in. tuft—and the foliage could only be seen here and there through the flowers on the other plants. The androsace was planted in 2ft. of ¼in. path gravel riddlings, with a little powdered leaf-soil added. This year a top-dressing of the above, plus silver sand and powdered charcoal, was given—with, to me, the amazing results I have described.

This has been a good year for the more difficult plants. Androsaces argentea, helvetica, Charpentieri, ciliata, pyrenaica and glacialis have all flowered well; Primulas Deorum and glutinosa have flowered and still seem flourishing.—C. C. MOUNTFORT, *Uppingham.*

GRAPE VINES and THEIR NEEDS

THE precise time at which vines should be started into growth should be governed by the time at which the crop is required, due regard also being paid to the capabilities of the heating apparatus. It may, however, be laid down as a general rule that a fairly late start is better than a very early start.

Before the eyes begin to break the prudent cultivator will take care to clean thoroughly both the rods and the whole interior of the vinery, for without a perfectly clean start there will be not the slightest chance of going through the season without trouble, and when, half-way through the season, cushion scale, mealy bug or other pests make their presence apparent it may very likely mean considerable damage to the crop in order to gain a mastery over the enemy.

All loose, frayed bark should be removed from the rods and trunks. It is of no service to the vine, but will prove to be a great harbourer of spores of fungi and eggs of insects.

Gishurst Compound is a well known and well tried article which makes a very effective cleanser of vine rods. It may be used warm, and with a small, soft-haired scrubbing brush, in just such a way that one would wash ordinary woodwork with soapsuds. The rods should be taken from the wires for the purpose of cleaning, and advantage should be taken of the opportunity thoroughly to clean the wires by rubbing them well with cloths soaked in paraffin oil.

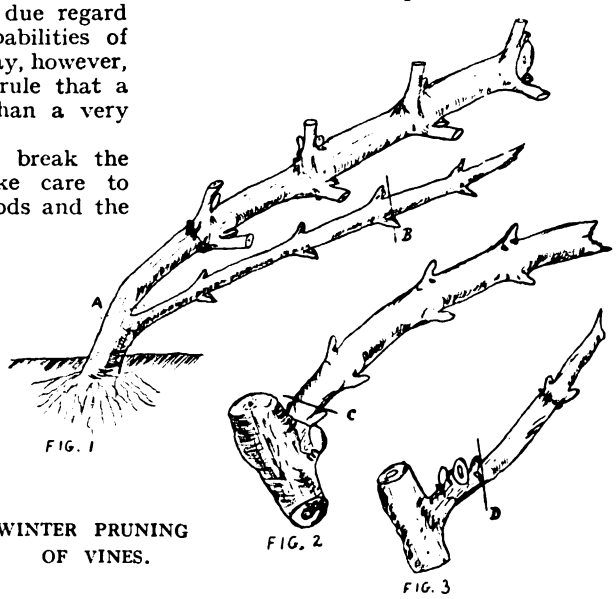

FIG. 1 FIG. 2 FIG. 3

WINTER PRUNING OF VINES.

Homco Soluble Paraffin, or some other properly prepared paraffin emulsion, is a good winter spray for vines, and may be specially recommended for cushion scale. Mealy bug is stubborn and tenacious, but it can with perseverance be routed by using a very strong mixture of Gishurst Compound, or of soft soap, to which a few drops of strong nicotine or of XL All Fumigating Compound has been added, the mixture being

Digitized by Google

worked into every joint and crack in the bark with a short-haired brush.

Before growth starts vines should be carefully pruned. Method of pruning will depend upon the age and condition of the vines. A newly planted vine should be cut back to the junction of the vinery roof with the wall. The strongest eye that breaks into growth (generally the first below the cut) is allowed to develop, the rest of the young shoots being pinched out. The longer the young stem grows the stouter it will become, and that is exactly what is wanted, albeit the following winter it must be cut back to within 4ft. of its starting point (Fig. 1). That is where many vines get spoilt, the owner's impatience inducing him to leave too great a length of the first season's growth.

The topmost eye on the shortened rod is again allowed to grow unchecked, and the lateral or side growths are also allowed to grow until they reach the fifth or sixth joint. The next winter the young rod is again robbed of from one-third to a half of its young growth, and the lateral shoots are taken right back, leaving one eye only to each (Fig. 2). The third year the main growth is left the full length of the roof, and no further extension is allowed. The laterals are again cut to one eye (Fig. 3). So long as the main rod retains a healthy condition the annual winter pruning will consist of shortening the laterals to one eye.

It may happen that one takes over an old vine which through neglect has got into a bad, unhealthy condition, and the question arises whether cleaning, nourishment and care will effect a speedy recovery or whether it will be better to sacrifice a year or two of fruit in order to cut out the old rod and lay in a young one. The method of procedure if the latter course is decided upon is, to saw through the old rod at 2ft. or 3ft. from its starting point, trim the edges of the stump with a very sharp knife, and seal over the wound with mastic, styptic or some similar waterproof preparation. Select the best eye that breaks and treat exactly as has already been described. The removal of limbs must not be undertaken after the sap becomes active in spring. A good plan where an old vine has two or three rods is to cut out one a year until the whole vine is rejuvenated.

The feeding of vines is another matter that must claim careful consideration. Vines make a large amount of growth and foliage, while the development of the berries involves absorption of much nourishment. Foods must be rich and not too rapidly soluble. Good dried blood manure is serviceable, and bone-meal is a favourite food for vines. This, however, is not applied to best advantage if merely scattered over the surface and left exposed, but if mixed with a quantity of good soil, leaf-mould or spent hops, and laid on a good thick mulch, first loosening the surface soil of the border with a rake, young roots will come up for the nourishment, and it is always a good plan to encourage surface rooting, so long as a watch is kept that they do not suffer later on from drought.

For many years Thomson's Vine Manure has held a sound reputation for its excellence as a nourishing food for vines, and very many gardeners and exhibitors have consistently used this manure with conspicuous success. Other well known firms also send out good vine manures, and there is no reason to question the value of any brand from firms of good reputation.

There is this one point, however, which may well be borne in mind—vines, appreciate and require change of diet. When a particular mixture of either chemical or organic manures has been used repeatedly it is well that something quite different shall be used for awhile. An excellent change from the proprietary fertilisers would be dried and finely pulverised sheep manure, while it may be beneficial once in a way to use a good ground lime instead of manure. Grapes require a considerable amount of lime; hence the customary advice that in making a new vine border a liberal quantity of old mortar rubble should be buried. Even this, of course, loses its virtue in time, and the lime supply then requires replenishment.

Liquid manure is suitable enough for vines if conditions are carefully studied. It is aggravating trouble to apply liquid manure to a sickly vine if the sickness arises from inactive roots, and it may be added that a very large proportion of the illness of vines does originate from root troubles. Defective drainage, causing sourness of the soil, stops, or at any rate checks, root activity, and drenching borders in that state with liquid manure will only make matters worse.

A. J. MACSELF.

BOTANY FOR THE BEGINNER—II

IN THIS AND THE FOLLOWING ARTICLE, THE LEAF IS DESCRIBED FROM THE POINT OF VIEW OF ITS STRUCTURE AND FUNCTION.

IN the preceding article the green plant cell and its simple organisation were discussed at some length and also the important rôle that the cell fills in the organic world. It was remarked that its vital activity was the same whether it acted as an isolated unit or was one of many cells all living and working together for the benefit of the whole—an excellent democratic scheme. It should be clearly understood that in the evolution of the higher and larger forms of plants from the simple multicellular green plant—wherein each cell carries out all its vital functions, including self-nutrition—it became necessary to assign special duties to particular cells, and hence many, having become fitted for other functions, are no longer green. With this specialisation certain organs were evolved in order to fulfil certain duties, and in the present article one of these, the leaf, will be considered. The discussion of this structure will enable us to follow the green cell still farther, and should emphasise its great importance in the life of the plant.

For a considerable number of years the root of the plant was generally regarded as the organ of nutrition, with the flower and seed as the organs of reproduction. The direct utility of the leaf in the life of the plant was not admitted, it being more or less looked on as an ornament of a somewhat showy description. It has now been recognised, however, that the leaf is as important as, if not more so than, the root in the direct nutrition of the plant. From what has been said of the green cell and its active constructive processes, and with the knowledge that myriads of these cells are to be found in every leaf, it will be clearly evident that the leaf embodies the very essence of a plant's life. Certainly those erroneous ideas which prevailed long ago are to be excused, since the physiological processes of nutrition which go on in the leaf are in a sphere of their own, with no counterpart in the animal world which occurs to the mind when dealing with this subject. Bearing in mind that the leaf is an organ of nutrition and, being composed to a large extent of green cells, depends on the energy of light to carry the process to fruition, we will examine the structure in order to discover the points which render the organ singularly well fitted for the performance of this all-important function. It may be defined as an organ which has been evolved to perform the double duties of nutrition and respiration, and arises as the natural outgrowth of the stem which bears it.

As is well known, it varies in size, shape and texture. A typical example will serve to illustrate the point if the reader can picture in his mind's eye the leaf of a horse-chestnut in comparison with that of a birch, or that of a maple with an oak, and so on. In the majority of cases it is a dorsi-ventral structure, that is to say, it is flattened on both sides. In its simplest form it is composed of three parts, the flattened portion being the blade or lamina, the stalk portion or petiole, and the sheath, which generally is to be found in the form of stipules or leafy expansions at the base of the petiole. Where the petiole joins the stem, there may be a small cushion—scarcely noticeable in some plants. This is the pulvinus. Another small cushion, known as the articulus, may also be found where the blade of the leaf joins the stalk. These two organs are the seats of movement in the leaf, and enable it to respond to wind, thereby reducing to a minimum the danger of mechanical injury. Associated with this reduction of risk of mechanical injury is the fact that the blade is enabled to increase in surface area, which, of course, is most beneficial, since, after all, the leaf is a sun trap, and the larger the area of green material which can be exposed to the air the better. Hence the reason why very large leaves, as well as possessing seats of movement, are subdivided into smaller areas termed leaflets,

Digitized by Google

as in the rose. This, arrangement while exposing a greater surface area for absorbent and nutritive purposes, reduces to a minimum the risk of damage by gales and storms of wind.

The most important function of these two organs, however, is in relation to the orientation of the leaf with the amount of light available. The leaf may not be exposed to bright sunlight. In fact, in climates such as ours, it rarely is; but it is always placed so as to absorb all that is available, even although the supply may be in excess of what it can utilise. One should have in mind, also, that as well as being suitably orientated to receive light energy, it requires to be placed in such a position so that it can secure a certain amount of carbon dioxide, the supply of which is limited. By a cursory examination of the leaves of a few shrubs or trees it will be evident that the position of the leaves is such as to prevent mutual shading. In nearly all species of plants the leaf arrangement is a constant one and can be referred to a definite mechanical system. Thus it may be recognised that, by turning and twisting, the leaf endeavours to present all its available surface to the light and air, and when a plant, such as ivy, is growing against a wall, the definite arrangement of leaves, which cannot fail to be noticed and remarked upon, is truly termed a leaf mosaic.

To a certain extent the leaf is supported by the branching framework of veins which ramify through its surface and which may vary in arrangement. In the great group of plants known as the monocotyledons, including such plants as irises, crocuses and all the grasses, the characteristic arrangement is to have a number of parallel veins traversing the leaf with a number of small cross connecting links. And if one recalls to mind the picture of a grass leaf it will be readily understood how such an arrangement is eminently suited to give support to this type of leaf. In the great majority of plants, however, we have one main vein—the so-called midrib—from which run innumerable small veins, which in turn give rise to smaller, ultimately forming a complete network. It resembles a river with its tributaries and streams. The main function of these veins, however, is not to give support and rigidity to the leaf area, but, as will be seen in a later article, to convey water and food material backwards and forwards in the plant body. G. C. T.

GARDEN TECHNIQUE

Notes on the Technical Side of the Garden and the Cultivation of Plants.

FLOWERS

MORISIA HYPOGÆA.

THIS is a choice subject for the rock garden, which flowered for the first time in 1834. It was originally introduced by a Mrs. Palliser, the plants having been raised from seeds sent to her by Professor Moris, after whom the genus is named. It is found on the mountains of Sardinia. It was, however, lost to cultivation, but reintroduced by M. Correvon about 1891.

M. hypogæa is one of the most charming rock garden plants, quite hardy, perennial, and not a difficult subject to deal with. It forms flat little tufts or rosettes of glossy leaves, and the flowers, which appear in April, are rich golden yellow, about an inch across, and are borne singly on stems 2ins. or 3ins. high.

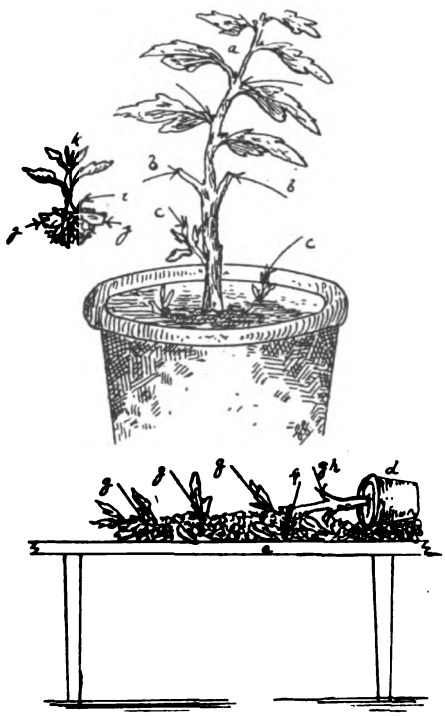
I have found it thrive best in a well drained, deep, light loam to which has been added a liberal quantity of old mortar rubble broken up fairly fine. A suitable position is where it finds tolerably cool root run, and, although a light spot is needed, it does not enjoy being baked by the sun.

The specific name hypogæa is derived from the fact of its burying its seed-pods in the soil, and the plants require watching very carefully if it is desired to collect the seeds. These should be sown directly they are ripe. Other methods of propagation, by cuttings or careful division, give successful results. It can also be increased by root cuttings. A few plants should be kept in pots until they become starved; then the roots are separated from the soil and the plant divided into small pieces. The thick parts of the roots may be cut into ½in. lengths, and these are placed in small pots, just covering them with sandy soil. If arranged in a cool greenhouse or cold frame, tiny plants will soon be produced.

M. hypogæa is an excellent subject for the rock garden, and very effective in pans in the alpine house or frame.—T. W. B.

"FIXING" A CHRYSANTHEMUM SPORT.

CHRYSANTHEMUMS sport more freely in some years than in others. And all over the country where these plants are grown, judging from enquiries I have received as to the right way to "fix" a sport, the plants are adding, probably, a few more gems to those we already possess. The sport duly "fixed" is, generally, similar in form to the one from which it sports, but instead of being weaker in constitution it is stronger. For the benefit of the inexperienced I will briefly describe what a sport is and how it is "fixed." A white-flowered variety may bear a yellow



flower on one stem. The variety W. Rigby first appeared on a stem of a plant of the variety Mrs. Gilbert Drabble. When the new flower is to be fixed the stem bearing it, as shown at *a* in the sketch, is carefully retained and all other stems, *b*, *b*, are cut off; also, any stem or root cuttings formed below that point, as shown at *c*, *c*, are discarded. If these were rooted the resultant flowers would be similar to the original ones in colour. The pot, *d*, is placed on a greenhouse stage, *e*, also the stem its whole length as shown, and fine gritty soil placed on 1in. deeper than the stem, so that all joints are covered with it, as shown at *f*. The desired young shoots grow up from the axils of leaf and stem as shown at *g*, *g*, *g*; *gh*, showing the stumps of the other stems. When the new shoots are 2ins. or 3ins. long, cut off the old leaf, *i*, and the stem, *j*, *j*. The new plant is shown at *k*; it is grown in the usual way and will bear the new colour—true to it as a sport on the parent plant.—GEO. GARNER.

THE CHRISTMAS ROSE.

THE Christmas Rose, to give the plant its common name, is much to be admired, being so hardy and thriving with a minimum of attention at a season of the year when flowers are most welcome. They were to be found in bloom at the end of November, while a plant of major or altifolius—an early flowering variety of the type—nestling fairly close to the base of a cupressus bush commenced expanding its blooms during the last week of October and is still in flower. It may be interesting to state that this plant flowered at the same time last year.

If flowers are desired for cutting, protection of some kind will be necessary, as continued rains detract considerably from their beauty. The flowers appear among the leaves, and therefore receive some natural protection. Each stalk bears one flower, although sometimes two are produced, but when this is found the primary flower is always the larger. In small groups—say of three clumps each—the plants when in flower look well and have a marked effect.—D. A.

ANCHUSA ITALICA DROPMORE.

MOST cultivators of hardy border plants know and grow this handsome alkanet, yet it may not be generally known that the leaves and crowns suffer much in severe weather. Therefore no time should be lost in having the plants protected, especially those that were planted out last month (November). In the past we have found weathered coal ashes heaped around and underneath the leaves of each plant to be a clean and ideal protective material, which keeps the plants safe throughout the winter.

The anchusas are plants which respond to generous treatment, and on well manured and deeply trenched ground they make luxuriant growth and flower profusely. Young plants can be raised from seeds sown in spring or throughout the summer. In addition to seed one can propagate from the roots of older plants. If one or two plants which have flowered are dug up any time during the autumn or early winter, the firm and vigorous roots—from ½in. to 1in. in diameter—should be cut into sections each

Digitized by Google

about 3ins. long. These should be inserted in boxes of medium fine sandy soil, keeping the top ends uppermost—a slanting cut having been made at the bottom end of each, where difficulty in knowing one end from the other is likely to arise. When each box is filled the top or flat end of each root—those being set vertical in the earth—should just show on the surface and be level with the soil. Place the boxes out of doors and cover them with coal ashes to the depth of several inches. They should be left thus until the green growths appear, when they should be exposed to light. In the month of April or May the young plants should be carefully separated, and set out in good soil in the reserve garden. —DAVID ARMSTRONG.

GREENHOUSE

PLANTS UNDER STAGING.

THE owner of a small greenhouse is always anxious to grow as many plants in it as possible: to make the best use of the structure and because he loves the plants and their flowers. But many greenhouses have their stages overcrowded with plants, while the borders underneath are left bare. There are many kinds of plants that will thrive just under the front portion of the stage and their presence helps, considerably, to furnish the structure. In the first place it is advisable to prepare a good border of soil, one averaging 7ins. in depth and 1ft. in width being generally suitable. In the warm greenhouse Tradescantia zebrina and Panicum variegatum do remarkably well, also Asparagus Sprengeri. The long graceful fronds peep out and look very charming, besides, they are also useful for cutting. A small quantity of peat should be added to the soil for these plants. Asparagus plumosus rarely does well in such positions. Adiantum cuneatum, the maidenhair fern, seldom succeeds under stages, but at the corners they will grow satisfactorily. Pteris tremula will grow remarkably well. If greenhouse ferns are not available, hardy ones will do nicely. Of course, flowering subjects should not be planted in such positions. I can strongly recommend selaginellas as green carpet plants for beds of this kind with or without other kinds of plants; the best time to plant is early spring; single fronds just covered at one end with soil succeed better than large tufts.—G. G.

FLOWER POTS, SEED AND SEEDLING BOXES, GARDEN VASES.

THE present is a good time for making a close inspection of the above, so that all may be cleaned and repaired and, where there is a shortage, buying in the necessary numbers so that they will be available next spring and the early part of the summer, when they are mostly filled with plants. Many thousands of flower pots are cracked and spoiled every winter through being exposed to the frosts, numbers of them being filled or partly filled with soil. When the thaw comes the pots are found to be ruined. All not in use should be emptied, washed, dried and stored in true telescopic fashion—the small ones fitted into larger—and stored in a cool, dry shed or, if outside, in a dry place and covered with boards. Very severe frosts will not harm them if they are kept dry. Old seed, seedling and cutting boxes should be examined, too. It may be that some of them are quite sound, others may have sound sides but rotting bottoms. All such, in my own case, are cleaned, after discarding the old bottoms, and new bottoms are fixed on the opposite side—the top. Boxes treated in this way will do service for another year. Every old box should be whitewashed inside to sweeten the wood and as a precaution against fungus. Boxes that are now covered with fungus, if only a little, should be burned. Summer flower vases should be emptied of soil and stored unless they are fixtures. Wooden ones, certainly, should be stored, cleaned and painted.—CHRISTCHURCH.

MID-WINTER TEMPERATURES UNDER GLASS.

I AM induced to write a note on this subject because I know it is a fact that many owners of new glass structures waste much good fuel in maintaining unnecessarily high temperatures during the wintertime, and they do this to the injury of the plants they wish to benefit. We grow stove plants in the structures which are heated most; warm greenhouse plants in the intermediate temperatures and ordinary greenhouse subjects in those structures from which frost and excessive damp are kept. If there is a miscellaneous collection of plants in one house, some requiring the highest and others the lowest temperatures, respectively, then it can only be safe to maintain a heat suitable for the tenderest kinds. The others may be made more tender for the duration of the winter, but they will survive and soon gain some robustness with the return of naturally warmer weather. If the reverse conditions obtained as regards internal heat, the tender plants would receive a very severe check, from which they would not recover to be, at least, normal again. Where there are cool greenhouse plants and means to apply heat, a little of the latter in the winter will do them good, not harm. But it is where fruit trees, such as vines, figs and peaches, are associated with ordinary greenhouse plants that great care must be taken about temperatures. Until late in winter, when the buds of the fruit trees begin to swell, the internal heat must be only sufficient to exclude frost.—HANTS.

MISCELLANEOUS

THE MISTLETOE.

ALTHOUGH the mistletoe grows comparatively easily in this country as far north as the fruit lands of central Scotland, yet it is comparatively rarely found, and, at this season, an immense quantity of it is brought across the Channel to all our large towns. We are not prepared to state that its culture might be a profitable business over here, but this we do know, that one plant will furnish all that is needed in any household for a lifetime at least.

As every reader knows, the mistletoe is a parasite. It is found growing well above the ground on apples, the lime, the black poplar, and less frequently on many other trees, including the plum, the rowan, the oak, the hawthorn, the plane and the sycamore. It is raised from seed sown directly on the tree; a branch some three or four years old is the best; a tongue of bark is cut, the gummy seed is squeezed from the berry inside this cut and left there. It is, as a rule, best to insert the seed on the underside of the branch.

Growth is very slow—perhaps the impatience of the modern gardener is one cause of its absence; the first season only two cotyledons or seed-leaves are produced, and for three or four years development is abnormally slow. Once it is well established, however, it is there for good. We cannot say that it is really harmful to its host; it may be, indeed, that there is a kind of symbiotic co-partnership where the one helps the other and both stand to gain; but there is many an apple carrying a mistletoe shrub and still doing well. It may be remarked here that this parasite does exceedingly well on the ornamental crab apples found in gardens and in no way detracts from their usefulness.

THE GENUS NOMOCHARIS

FEW gardeners, probably, have heard of the nomocharis, a genus of liliaceous plants that lies between the fritillaria and the lily. These three genera form a close cohort and show distinct signs of a common ancestry, which is undoubtedly the reason why certain of the species when originally described were included among the fritillaries or lilies. In the latest number of the Notes from the Royal Botanic Garden, Edinburgh (Vol. xv, No. LXXI, H.M. Stationery Office, June, 1925, 4s. net) will be found an excellent revision of the genus by Mr. W. Edgar Evans, B.Sc., F.R.S.E., which follows and enlarges on Sir Isaac Bayley Balfour's original paper on "The Genus Nomocharis" (Trans. Bot. Soc., Edin., XXVII (1918), page 273).

After examination of much new material collected by Forrest, Ward and Farrer, and of some old that was not available in 1918, Mr. Evans found that Sir Isaac's general treatment of the genus was sound, but that a certain amount of additions and changes were necessary. The main additions are the description for the first time of two species, Nomocharis euxantha (Smith and Evans) and N. basilissa (Farrer); while the changes are the transference to nomocharis of six species from other genera and the reduction of four reputed species of nomocharis, N. Wardii, N. Farreri, N. leucantha and N. Forrestii. This leaves twelve species in the genus and three varietal forms.

It might be imagined that nomocharis is a genus for the botanist, for up to the present it has not responded happily to garden cultivation. Luckily, it is being found that, with experience, it is not such a difficult plant after all, and I have visions of its gracing many a garden during the next decade. Undoubtedly they are among the most graceful plants that the East has given us, both in the flower—wherein it differs from the fritillarias, as Mr. Evans points out, in the more open dice-box-shaped perianth—and in its habit and growth. Certain Asiatic genera, such as cremanthodium, have not proved amenable to garden treatment, although they have been tested in every conceivable position and by every possible method. Early growing specimens of Nomocharis pardanthina, the first to be introduced, proved small, sickly plants with very inferior stamina. Further experience, however, has shown that considerable depth of soil is necessary for their successful cultivation. At the Edinburgh Botanic Garden they have shown an odd method of growth. A long root is sent out from the bulb, on which another bulb forms about half-way down; the remainder of the root dies back to the secondary bulb. In succeeding years the same process occurs. In fact, the plant runs by means of these secondary bulbs, and a considerable amount of space must, therefore, be allowed it in order that it may move as it wants. In the past it has been treated as a rock garden subject, which is wrong. I have never seen it or heard of it growing anywhere else but on open alpine meadows.

Three species are at present in cultivation—N. pardanthina var. Farreri, N. Mairei and N. saluenensis var. purpurascens. They are all confined either to botanic gardens or to a few private gardens. The latest information, however, about their progress is distinctly encouraging, and it is to be hoped that in a year or two they will be distributed and so trickle into the ordinary garden. The distribution of nomocharis is not wide. One species is found on the western Himalaya, another in Sikkim and general alpine Himalaya, while no fewer than nine species are found in the tangle of mountains where Szechuan, north-west Yunnan and south-east Tibet meet. Two varieties and three species have been found in Upper Burma. This narrows down the main home of the nomocharis to quite a small area, much of which, however, still remains to be thoroughly ransacked, so in the future we may expect further finds in this fascinating genus.

Mr. Evans is to be congratulated upon the lucidity with which he has set a puzzling genus in order. His descriptions and arguments are clear and to the point and appear to be unassailable. One of his great difficulties has been the absence of living material, and I am sure that he would be grateful for any living specimens that could be sent him. The paper is illustrated with fourteen excellent reproductions of herbarium sheets of the various species and variety. These photographs were taken by Mr. R. M. Adam. E. H. M. C.

ONE SECRET OF ROCK GARDENING

BY HALLIWELL SUTCLIFFE.

ROCK gardening has now been followed as a serious pursuit for a full generation, and a contrast of to-day's efforts with those of thirty years ago shows an astonishing development in taste and in imagination. But there is a tendency, among certain amateurs who construct their own gardens, to grow formal and stereotyped in work that asks for free, natural handling.

I have known many people, keen gardeners, who declined to interest themselves in rockwork, simply because they had seen so many uninspired efforts. They did not refer to such old-time enormities as the almond-cake gardens, with the stones pointing skyward like so many monoliths. They were thinking of gardens where the rocks were laid truly, the pockets nicely ordered—but all of it too set to a rigid plan, somehow.

The root cause of this conventionality is that your rock garden enthusiast, oftener than not, thinks of first things last. His whole mind is preoccupied with the plants he intends to put there—for their beauty, their rarity, or the colour scheme he is developing. The rocks must be there, of course, because they give shelter, moisture and a frame to these plants he cherishes.

The rocks must do that, and much more beside. They are not humble servants of the garden scheme. They are its adornment and its first concern. The rock garden, indeed, in its nakedness—before ever a plant finds shelter there—should be a place of character and charm. And here one must stress once again the necessity of making friends with the rocks in their natural homes among the wilds.

Many people have imagination enough to give personality to trees, making sentient beings of them. It is astonishing how few have learned a like understanding of the boulders strewn broadcast on our northern uplands. The knowledge is slow to come and hard to win; but, once the intimacy is yours, it is absorbing in its wonderment.

You have learned by this time to be lukewarm about the arrangement that lays smooth stones, however charming their shape, in patterned order and makes artificial pockets by filling the interspaces with soil and limestone chips. Your ardour is centred on rocks whose own fissures are the pockets, and the completed garden, big or little, is a thing of natural, unstudied charm.

Perhaps in no other pursuit is there such comradeship to be found as holds between garden lovers—such readiness to exchange views and sound advice. For your real gardener, as distinct from the man who is merely proud of a display, would have every man's plot thrive to its utmost limit, so that the world should be richer by one more haunt of comeliness and peace. It is this confident freemasonry, I think, that makes another's hint at once so valuable and so readily accepted.

Casting my mind back along the years, I recall quite clearly the moment when my own unexpressed instinct for what one may call the wilder rock gardening found expression. The interpreter was an old, simple-minded countryman—himself the diligent cultivator of a little garden strip that he made magical each year—and he looked quizzically at my rock garden.

" It's all very pretty to them as understands it," he said at last, " but it has a foreign sort of look to me."

His keen eye suddenly detected something that brought a chuckle of delight. A spray of white arabis—the homely, single kind—was blooming free from a cranny of one rock less smooth and conventional than its neighbours. It had sown itself, and was no arranged affair of mine.

" I've always had a fondness for white rock, as we simple folk call it," he went on, " but I never saw it fair in its pomp till now. It's at home—just at home."

Nor had I seen the plant so likeable, now he brought it to my notice. It was indeed " fair in its pomp "—a delectable and dying country phrase—and was as unlike arabis in a usual border as if it were almost of another species.

There was the case of the house-leek, too. I found a big fellow rioting on the roof of a cottage, derelict long since in a wild cleft of the uplands. I transferred him to an honoured place in the rock garden, in a pocket of the usual sort. He did not grow less, certainly, or pine away; but his rough beauty was rendered almost commonplace. He seemed, I fancied, to have all the feeling of one who knows himself ill-dressed, for rocks are in truth the clothes of their plants. So then I sought better quarters for him, found a wide, deepish cranny; and there he lords it manfully, islanded by the grey boulder face on which he constantly encroaches. He is at home, and knows it.

EFFECTIVE PLANTING IN THE ROCK GARDEN.

All the sedums thrive in these natural pockets. So do the saxifrages, tucking their filament roots into the limestone's pores. They are always moist, and never by any chance can run mad with lush growth in rainy seasons. They grow compact, delightful to see in their frilly green, and bloom so lavishly that you almost fear they must die of their wild colour song of joy. Apart altogether from their blossom-time, two of these saxifrages especially give a feast if well matched foliage the year through. One is the crimson-flowered variety. The other is known colloquially as stag moss. Give one bold corner of your garden to these two. Plant them in boulder pockets. Let them run in and out together like friendly neighbours, never encroaching on each other or stealing too much of the grey rock that gives the soft, reflective tones to all their eager green. The stag moss throws up stout, antlered foliage; the crimson saxifrage, lowlier in growth, is compact and good to see, a dancing floor for elves when they creep out o' nights.

The primrose clan works happily into this scheme of gardening. It asks for deep, loamy pockets of the usual kind rather than natural clefts; but these can be formed in the spaces between each boulder and its neighbour, keeping, in this way the continuity of design. Different members of that family not only thrive in such conditions, but show their beauty with an appeal astonishingly fresh and urgent. There is a pink variety. I believe it has not been settled in our corner of the highlands for more than a generation, but it has spread so far and wide among our gardens that some name it the dale primrose. Wherever it grows it is a joyous thing, flowering even in our northern climate not long after such

NATURAL GROUPING OF ALPINES IN THE ROCK GARDEN, SHOWING THE ADVANTAGES OF DRIFT PLANTING.

optimists as the snowdrop and its own cousin, the Cashmere primula. But to see its rarest charm, plant it among boulders. The grey, ancient rock and the young eager clumps of bloom are in delicious harmony.

This type of rockwork has one most practical advantage. It is its own weed-killer. No deep-rooted aliens—dandelion, the dreaded gout weed and what not—can push their way through the solid stone. The only weeding asked is concerned with the plants themselves, when they encroach too far and threaten to upset the nice balance between grey rock and leafage. And the golden rule in this periodic thinning is, I think, always to have plenty of the rock exposed. It should be the sea, rather than the islands, in this scheme of emerald and grey.

SOME NIVALIS PRIMULAS FROM TIBET

IN a previous article I dealt with the primulas of the sikkimensis and candelabra sections collected in Tibet in 1924. I come now to another section of garden favourites—nivalis. Of forty species of primula collected, eight, or 20 per cent., belong to this section. Hence it is evident that for the general relationships of our Tibetan primulas we must look eastwards, where this section is well developed, rather than westwards, where it is poorly developed.

Indeed, of the eight species found in Tibet, four are actually Yunnan plants, namely, P. sino-purpurea (K.W. 5731), P. rigida (K.W. 5801), P. pulchelloides (K.W. 5887) and P. pulchella (K.W. 6080). The two last named are, in Yunnan, limestone plants, P. pulchella coming from the Likiang district, P. pulchelloides from Atuntzu. The Tibetan plants, on the other hand, were found on igneous soils. P. rigida is a dwarf alpine, very like the Chinese P. minor, which has been in cultivation. We gathered seed of P. sino-purpurea, P. rigida and P. pulchelloides, all of which are doing well.

K.W. 5731 is structurally indistinguishable from P. sino-purpurea, as I am informed by Professor Wright Smith. But P. sino-purpurea from Yunnan is a rather drab purple, whereas the Tibetan variety is a real high-tension electric blue. It grows in rather boggy alpine pastures on the rhododendron moorland at 14,000ft. With it is found another nivalid, with blatant purple flowers, K.W. 5745. This latter is a microform of P. nivalis, and has been named P. ningiuda. Seed was obtained. P. rigida was local, and we found it in only two places on bare wind-swept alpine grass slopes at 15,000ft. Here the soil is gravelly and well drained. The plant does not exceed an inch in height, but the flowers are large, mauve or purple with white "eye" and very fragrant. We gathered seed from one locality only.

P. pulchelloides was widely distributed north of the Tsang-po, growing under bushes of scrub oak and rhododendron, on well drained, gravelly banks. It likes shade, and flowers early in June. The seed has germinated very freely, and the young plants look remarkably robust. Thriving at a reasonable altitude, 10,000–11,000ft., it should be quite hardy, and it does not need lime. The Yunnan form is in cultivation.

More interesting was another species not seen in flower, K.W. 5973. This was found in the latter half of July growing in the spongy moss carpet of the Picea forest at an altitude of 12,000–13,000ft., though later I found it extending well into the alpine region on sheltered grass slopes. Rich loam and shade are its requirements.

All the primulas mentioned so far, with one unimportant exception, come from the region of dry winters and wet summers, a region covered largely with coniferous and rhododendron

Digitized by Google

forest, but with a rich herbaceous alpine flora. Nearly two-thirds of the total number of primulas collected come from that region.

I come now to a species collected in the region of wet winters and wet summers, or perpetual precipitation, the winter precipitation in the alpine region, of course, taking the form of snow. This region is covered everywhere with forest, and even in the alpine region with woody plants (dwarf rhododendron), so that herbaceous alpine plants are fewer. Though primulas were rarer here, they made up in quality what they lacked in quantity.

It was here that we found the extraordinary P. falcifolia, K.W. 5839. I include it because Professor Wright Smith is convinced that it is a nivalid. P. falcifolia has some obvious nivalid characters, such as the narrow strap-shaped leaves and the swollen rootstock, wrapped round by mucilaginous leaf bases. The flower might certainly pass muster as a nivalid. The reduction of the truss to one or two flowers, though unique, is foreshadowed in the lovely P. Coryana, which rarely has more than three, as is also the pronounced obliqueness of the corolla.

THE REGION OF DRY WINTERS AND WET SUMMERS.

The nivalid capsule is diagnostic, and P. falcifolia does not possess it. The capsule of P. falcifolia is globular, and the top comes away exposing a cup full of seeds (which, however, *do* resemble nivalis seeds) as in a typical candelabra (not that P. falcifolia is *that !*).

Anyway, nivalid or not, P. falcifolia with its large single or twin daffodil yellow fragrant flowers is a beautiful object. It is a bog plant—at least in the summer, from 12,000ft. Grown in a bog all the year round, it might survive those more violent changes of temperature and humidity to which it will be subject here. It needs no lime.

The daffodil primula is worth taking trouble over, though it will probably never be a popular plant. It has the curious property of flowering either in June or in October, though no individual plant flowers at *both* seasons. The winter flowers differ from the summer ones only in being scentless.

The relationship between the Chinese and Tibetan nivalis primulas extends also to those curious species which centre round P. Maximowiczii. At the Primula Conference in 1913, Professor Balfour said, referring to these primulas: "The nivalis section has developed a distinct race in north China." Some years later I found P. szechuanica west of the Mekong, in a district which could by no stretch of the imagination be called north China. Much more surprising was it, however, when not only P. szechuanica, already convicted of vagrancy, but also P. Maximowiczii itself turned up on the eastern Himalaya, over 400 miles west of its original locality. We shall have to revise our ideas on the distribution of these primulas.

P. Maximowiczii, K.W. 5817, differs from the type chiefly in the fact that it is, like so many of our Tibetan plants, fragrant. We met with it on steep, broken, forested slopes at about 12,000ft. It is a big plant, 3–4ft. high, with three whorls of dark chocolate flowers and coarse fleshy leaves, brightly silvered on one side. Seed has germinated well.

K.W. 5972 is the margarine-coloured P. szechuanica, another lanky monster, larger than the type, from which it also differs in being fragrant, at least the specimens I collected in Szechuan were certainly not scentless. We found it growing among rhododendron scrub and on the margin of forest at 13,000–14,000ft. It likes a gravelly well drained soil and shelter rather than shade. The seed has germinated well, and both this and the last named are handsome plants in spite of their flowers.

F. KINGDON WARD.

ODONTOGLOSSUMS FOR AMATEURS

BY GURNEY WILSON.

THE high prices realised for certain varieties of Odontoglossum crispum in years gone by rendered the cultivation of these plants particularly interesting, as both commercial and amateur growers secured handsome profits when disposing of propagated pieces. This craze for spotted and blotched varieties has long since ceased, and the demand for imported odontoglossums has practically come to an end. But, the interest in this genus still remains and is now attached to the first-flowering of seedlings raised in this country from carefully selected parents. Fine forms of Odontoglossum crispum have been produced in quantity and can now be obtained at quite reasonable prices. Not only has the formation of the flowers been improved, but the plants themselves are much more vigorous. This essential point of strong constitution not only gives rise to the production of more flowers on the spike, but to flowers of a thicker texture and, consequently, of a more lasting nature.

Only a few years ago all sorts of crosses were made, and with many inferior results. In cases when these seedlings produced nothing good, they had an educational value, for they taught the hybridists what not to cross. From the multitudes of different seedlings which have flowered in recent years it has been possible to determine the species that produce the best offspring, and to-day the careful selecting of parents is more than ever recognised as a very important matter. One of our leading hybridists once very wisely remarked that the very first thing to consider is the constitution of the plant: it is no use creating hybrids unless they can be grown in an amateur's greenhouse. The importance of using not only fine varieties as parents, but, more especially, plants that possess a vigorous constitution, is fully realised to-day, and in it lies the secret of the present popularity of odontoglossum hybrids. In gardens where it was formerly considered a difficult matter to grow orchids successfully, an entirely different opinion now prevails, for, with only the simple means and attention in use for the ordinary occupants of a greenhouse, it has been found that odontoglossums thrive amazingly. This change has been brought about, not by the creation of more skilful cultivators but by the production of a race of plants eminently suited to the requirements of amateurs and to the atmospheric conditions of their greenhouses.

With regard to temperature, it will be found that odontoglossums succeed best when the thermometer does not fall below 50° Fahr. During severe weather no harm will occur

Digitized by Google

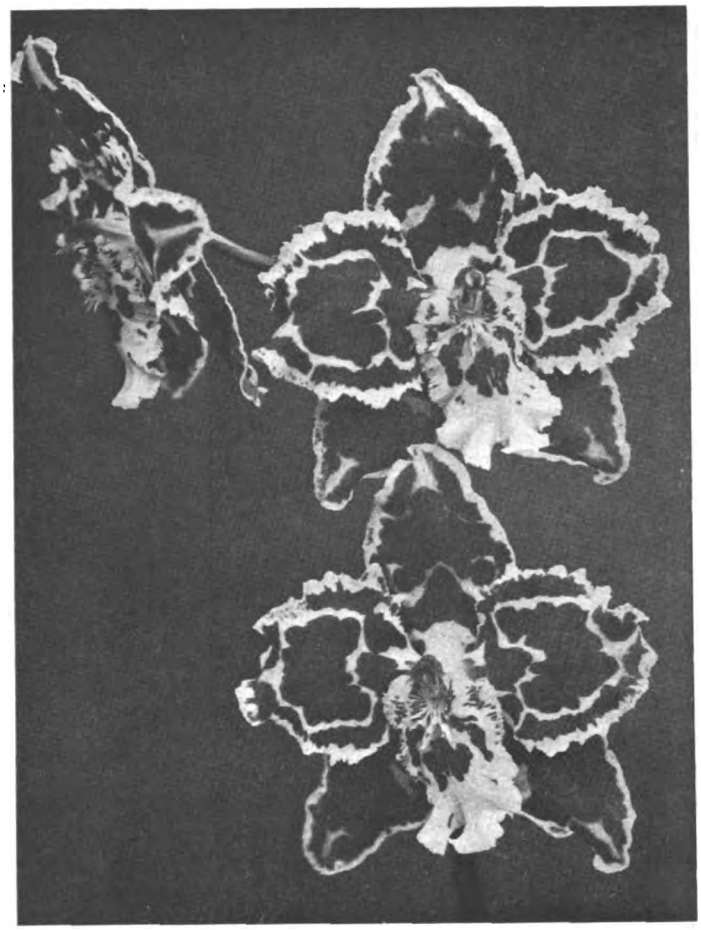
if 45° is occasionally registered. Many instances are known when the plants have safely withstood still lower temperatures, but it must always be remembered that the ambition of the cultivator should be to grow and improve his plants, not merely to keep them alive in a semi-dormant state. Generally speaking, odontoglossums commence their new growth in the autumn, continuing their activity right through the winter, and completing the bulbs in the early spring, after which the flower spikes are produced.

The natural habitat of odontoglossums is on mountain ranges in South America, where the atmosphere is buoyant and moist, and at an altitude where the temperature is fairly constant throughout the whole year. On that account the greenhouse in which they are being cultivated should be protected from bright sunshine. It may be said with a considerable amount of truth that the most anxious time for the cultivator of these plants is during the hot months of summer, when it is frequently impossible to keep the temperature down to a reasonable figure; any continuance of over 75° Fahr. has a weakening effect. However, this need not unduly worry anyone, for the cooler weather of autumn very soon rectifies matters.

The fact that a plant happens to be an orchid in no way implies that it must be coddled up as a delicate thing. For odontoglossums the atmosphere should at all times be moist and of a temperature varying between 45° and 60° Fahr. in winter, according to the weather, and as cool as possible during the summer. Ventilation is an important part of the cultivation of these plants. Fresh air should be judiciously admitted by means of ventilators placed beneath the staging and, if possible, below the level of the hot-water pipes. Too frequent use of the top ventilators allows the atmospheric moisture to escape, which should be avoided as much as possible. Frequent damping down of the floor and under-stagings is of much use in creating the necessary moisture. One might continue giving detailed instructions for every week in the year, but amateurs who can grow maidenhair fern—and who cannot?—will succeed equally well with odontoglossums, for they require almost similar atmospheric conditions.

Mention has been made in previous articles of how cypripediums and cymbidiums succeed in a loamy compost, or in a mixture of loam and fibre. But odontoglossums are much more particular as to the compost employed. On no account should any loam be used, or any substance of a similar nature. Nothing surpasses a mixture of fibre and sphagnum moss. Peat sufficiently good for orchid cultivation is now almost unobtainable and its place has been taken by other fibres, procurable from the trade orchid growers and sundriesmen. In practice it will be found that the smaller plants grow best when potted in a compost of three-quarters fibre and one-quarter sphagnum, but the larger plants do not require so much moss—a soft compost not being conducive to the production of flower spikes. Generally speaking plants of flowering size require re-potting annually, at a time when the new growth is a few inches high and about to send forth new roots. Young seedlings which continue in active growth without flowering require attention more often, say, every six or nine months. One cannot omit to mention the importance of using clean fibrous compost and also of packing it firmly in and around the roots. If the plant is held up by the bulbs and the pot falls off then the compost has been filled in much too loosely. A potting stick, such as can be made from the handle of a toothbrush, is necessary to accomplish the task in professional style. The final item consists of neatly trimming the surface of the compost with a pair of scissors.

While the home-raised forms of Odontoglossum crispum are the most popular of the species, there are innumerable hybrids suitable for the amateur. One may mention Odontoglossum amabile, ardentissimum, Rolfeæ and, in fact, all hybrids containing such well known species in their parentage as crispum, Pescatorei and Harryanum. When we take into consideration that about one thousand different odontoglossum hybrids have been recorded, there can be no doubt whatever as to the great popularity which this genus enjoys, and the amount of material from which amateurs can make their selections.



A TYPICAL ODONTOGLOSSUM HYBRID OF O. CRISPUM PARENTAGE.

SERVICE FOR READERS

Though so many subjects are dealt with in each issue of THE GARDEN, it must constantly happen that readers seek information which is not immediately available. In such circumstances they should make use of our Service Department. Through its medium each reader's own particular enquiry can be dealt with. No matter what the question is, whether advice is sought as to—

RESTOCKING A GARDEN, COLOUR SCHEMES FOR GARDENS, THE BEST PLANTS FOR CERTAIN SITUATIONS, WHERE TO OBTAIN NEW AND RARE PLANTS, INSECT PESTS, NAMING OF PLANTS, AND THE HUNDRED AND ONE OTHER DETAILS RELATING TO THE GARDEN—

there is always information available from a staff of expert contributors and consultants; *and there is no charge for this.* It is one of the additional means of Service which THE GARDEN is glad to render to its readers.

Also, there is the further convenience which the Service Department affords of supplying readers with data about anything that is advertised in the pages of the paper. Thus, on receipt of an enquiry, particulars will be sent of, say, half a dozen things about which the reader seeks information. The only stipulation is that a stamped addressed envelope shall be sent with the enquiry.

All communications should be addressed to the Service Department, THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C.2.

NOTES OF THE WEEK

ROSE HARRY KIRK.

NOW that we are once again in the midst of the rose-planting season I should like to draw attention to an old and, I fear, rather neglected variety, namely, Harry Kirk. This, in the writer's opinion, is one of the best garden roses in existence, and it is certainly his favourite yellow, though, of course, it cannot vie with some of the modern varieties in brilliance of colouring. The buds are a deep sulphur yellow marked on the outside with crimson, but, on opening, the colour fades to a primrose yellow, and the flowers are produced with great freedom far into the autumn. It is a vigorous grower and makes a fine bedding rose, while it makes a beautiful standard, for which purpose it comes a close second to the ever popular crimson Hugh Dickson. It seems a pity that this reliable and beautiful hybrid tea should receive so little attention—it is seldom mentioned nowadays in articles on roses in the gardening papers, but, unfortunately, the present craze for brilliant colour seems to be pushing many well tried favourites into the background, though were I to be confined to six varieties only, Harry Kirk would undoubtedly be one of them. Probably, however, most readers of THE GARDEN will disagree with me. Lest critics may suggest that I have not tried the modern yellows, I may say that Golden Emblem, Mabel Morse, Souvenir de Claudius Pernet and Christine have been, or are at present, grown in our garden, but the subject of this note has not been displaced in favour.

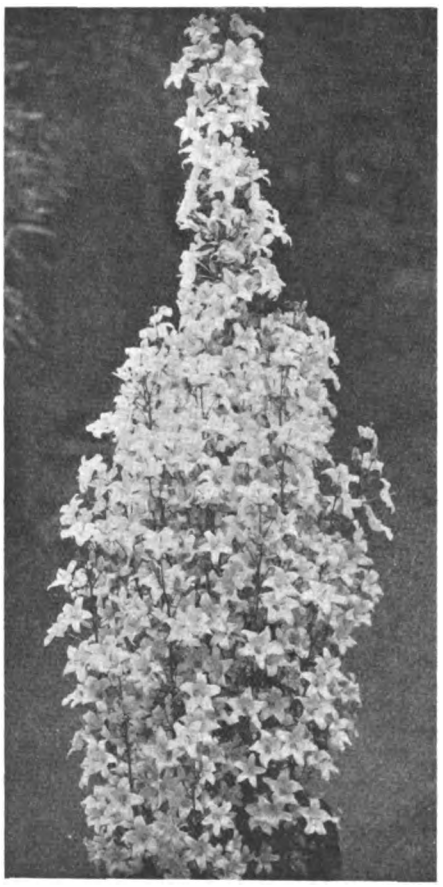
Of these four sorts Christine is the most reliable, though smaller in size of flower; Golden Emblem and Mabel Morse are uncertain and, with us, by no means free flowering; while Souvenir de Claudius Pernet is not so attractive either in foliage or colour.

I hope some readers of THE GARDEN who may be making a selection of roses for present planting may be encouraged by this short note to include a few plants of Harry Kirk in their order, and if they do, provided vivid colour is not their chief aim, I do not think they will be disappointed.

Of course, it must always be remembered that it is a case of different roses for different gardens and districts, and that I can only vouch for Harry Kirk's good behaviour with us, situated in the North of Ireland; but the same applies to all rose growers who recommend their favourites, and consequently I venture to contribute this note.—CECIL M. BAILEY.

OCTOBER ROSES.

THE following roses were in bloom during October in a Sussex garden: Mme. Lambard, Parfum de l'Hay, Lieut. Chauré, C. V. Haworth, Catherine Mermet (a still indispensable old rose, far superior to many modern varieties in vigour of growth and freedom of flowering), President Wilson, Alexander Hill Gray, André Gamon (a little known, but in my opinion absolutely indispensable rose with a sweet, luscious scent), Argyle (another variety seldom heard of but which is especially good in autumn, fully formed and well scented). Diadem is a comparatively new rose, which hardly comes up to its catalogue description either in colour or constitution. It is a poor grower, but is, nevertheless, a good autumnal variety. Conrad F. Meyer and Commandant Félix Faure, both generally considered to be summer blooming only, have given some good flowers lately, so also has that sweet-scented old crimson Comte Raimbaud and that equally old favourite Marie Baumann. Laurette Messimy is always good. Raymond has been full of its somewhat variable flowers. Etoile de Hollande, Etoile de Luizante and Etoile de France, which last has many buds even at the date of writing (October 28 h), but they seem to make a poor job at opening them. I imagine Etoile de France would be good under glass. General McArthur, Rouge Angevine, Benedicte Seguin and, best of all, that beautiful old scented yellow Harry Kirk, the fragrance of which is far more pronounced in autumn. Among the ramblers a dear old rose named Seven Sisters has had masses of panicled bloom (and is still in bud) almost white with distinct china pink shading. What modern rambler can beat it? To-day I notice blooms of Hadley which lasts well indoors, and the half-opened buds open out to perfection



THE STATELY CHIMNEY BELLFLOWER
C. PYRAMIDALIS.

in water, whereas many roses fade more quickly in autumn when cut from the open border; Willowmere, the last of Mary Countess of Ilchester, an excellent and never-failing autumnal; Earl Haig, one of the most floriferous; Prince of Wales, Padre, Dr. Joseph Drew, National Emblem, A. R. Goodwin, Severine (in bud), Safrano, Socrates, Cecile Brunner, Armosa, Ducher, the old pink China or monthly rose Etoile Luizante, showing another crop of its brilliant pink buttonhole flowers; and Souv. de Georges Pernet, surely the most consistent and certain of all autumnal blooming roses, for its blossoms are as perfect on the threshold of November as they are in the middle of summer. It lacks one thing only, *viz.*, scent. Captain Cant, Captain Kilbee Stuart and Grand Duc de Luxembourg are full of buds if the weather remains propitious for their opening.—EDWARD SHOOSMITH.

THE TALLER CAMPANULAS OR BELLFLOWERS.

THE genus campanula contains a host of species and varieties of unusual merit, largely grown in the border, rock garden, and for greenhouse decoration. They naturally divide themselves into two groups, tall and dwarf, the latter being adapted for the rock garden and walls, and the more robust are suitable for the front of the herbaceous border.

In the present note I shall draw attention to the taller species, which, owing to their vigorous constitution and height, lend themselves readily to conspicuous positions in the border, the shrubbery, and near woodland walks, providing they are not too heavily shaded. The campanulas under notice enjoy a well cultivated border—one that has been dug deeply and not too heavily dressed with manure. In dry shallow soil they do not grow so luxuriantly, probably through lack of moisture at the roots, and when this occurs the stems lose their lower leaves prematurely, while the whole plant is often attacked by thrips or red spider. This drawback, however, can be overcome to a certain extent by affording a heavy mulch of partly decayed manure early in the season, and an occasional application of water if the weather proves very dry. Sufficient moisture must be given to wet the roots thoroughly, a mere sprinkling being useless.

One of the best of the tall campanulas is C. lactiflora, a plant not seen as often as its merits deserve. It is a stately subject with stout stems 4ft. to 5ft. high, freely branched, and has loose spreading panicles of pale blue flowers. The white variety, alba, is a very effective border plant, being a counterpart of the type except in colour; while the form known as E. Molyneux is blue, and attains a height of 2½ft.

C. latifolia is well known, the stiff stems attaining a height of 3ft. to 5ft. The rich violet-purple flowers are disposed in spicate racemes, and are long tubular or trumpet shaped. In the variety alba the flowers are white, and the pale blue Burghalti produces large drooping flowers 2ins. to 3ins. long, and the stems grow about 3ft. high. A very beautiful variety is Van Houttei; and macrantha, with its handsome purple bells, is a fine bold plant for the herbaceous border. Owing to the strength of the plants, stakes are rarely required, and this fact is worth noting, because many border subjects are robbed of much of their beauty and general effectiveness by bad staking. C. latifolia produces seeds freely, and as a rule a number of strong seedlings appear in proximity to the parent plant.

C. pyramidalis and its variety alba is grown extensively in pots for the cool greenhouse, and, moreover, it comes in extremely useful for groups at flower shows during July and August. It possesses great merit, however, as a border plant, and any doubt in regard to hardiness should be dispelled. It is a vigorous plant, readily raised from seeds sown in March, while it can also be increased by root cuttings. The spikes of blue or white flowers are 5ft. or 6ft. high, but the Sion House variety is more dwarf in habit.

C. grandis is suitable for the front of a border, being about 18ins. high. The pale violet-blue flowers are broader than most campanulas, and the habit of the plant is rather distinct. It is readily increased by division.

Perhaps the most popular section of the group under notice is the peach-leaved bellflowers, of which C. persicifolia is the type. This plant reaches a height of 2ft. to 3ft., the flowers are blue and over 2ins.

Digitized by Google

across. There are several fine varieties of C. persicifolia, and most of them are worthy of a place in every collection: all they ask for is ordinary good garden soil. One of the best forms is Telham Beauty, which has been honoured with an award of merit from the Royal Horticultural Society. It produces large flowers of a pale china blue in abundance, and is a free grower. I have raised this plant from seeds, and the majority were quite up to the standard of the A.M. form.

Another distinct variety is Moerheimii, an excellent double white; while humosa is a double light blue. Both are acquisitions.

Daisy Hill is semi-double and a delightful shade of lavender-blue, and so is Iris Carlile, which has pale porcelain blue flowers. I have heard good reports of Wargrave Blue, with semi-double flowers of a deep violet blue, and I shall certainly give it a trial.

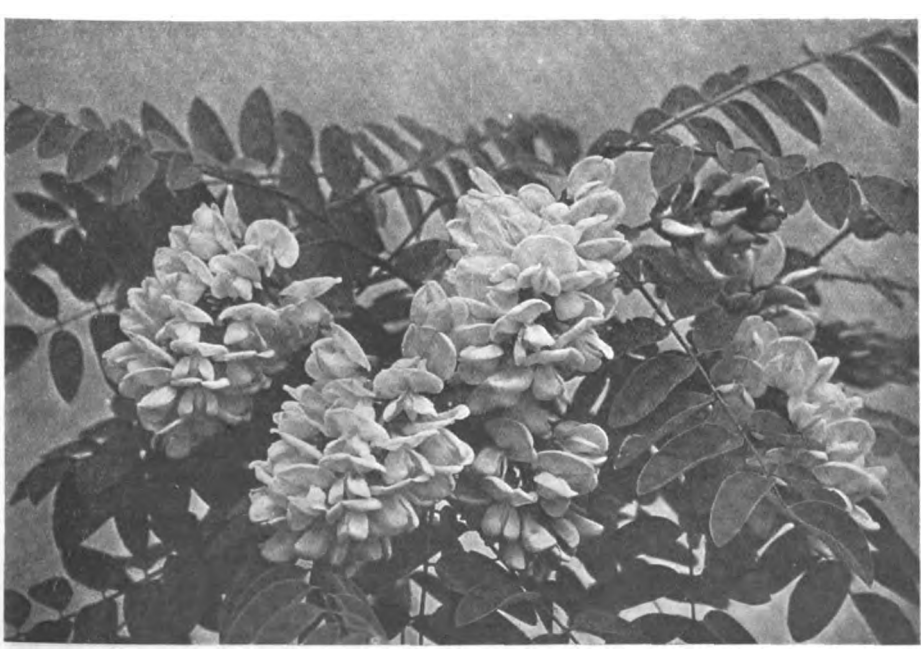
The last but by no means least on my list is C. glomerata dahurica, a handsome herbaceous plant admirably suited for massing, especially where a feast of colour about 18ins. high is desired. It produces clustered heads of flowers of a rich deep purple well over 2ins. long. Other varieties are superba, acaulis and alba, but the one noted above is about the best. All these plants can be increased by division, but C. lactifolia may be multiplied by cuttings of the young shoots that appear on the stems.—T. W. B.

CAMPANULA TELHAM BEAUTY IN THE HARDY BORDER.

THE CLAMMY LOCUST AND ITS HYBRIDS.

WHEN travelling in central Europe, especially in eastern countries like Hungaria, one would not believe that the locust is not a native European tree. Since its introduction from North America shortly before the middle of the seventeenth century, it has made itself surprisingly at home in almost every part of Europe. In the Hungarian plains it forms at present the most conspicuous part of the woody vegetation, and quite often it has become almost a weed on sandy soil or even in well kept woods. At the end of May and the beginning of June when the plants are loaded with their dense white racemes, the locusts are of great ornamental value. Besides the type there are a few very striking forms of Robinia Pseudacacia, such as var. tortuosa, with its strangely twisted branches or var. Ulriciana (or Rozynskiana) with somewhat pendulous branchlets and rather long pendent leaves, which give the tree a very curious appearance.

The common locust is a tree widely spread throughout the eastern part of the United States. The other arborescent locust of the east, the clammy locust or Robinia viscosa, is, however, scarcely known in a wild state, being met with, according to Britton, only in a few localities in mountain woods from North Carolina to Alabama. It was sent to Europe by the famous French traveller, Michaux, in 1791, and as a smaller tree it is of even greater ornamental value than the common locust. It has its Latin name, R. viscosa or R. glutinosa, from the sticky glands covering the young twigs. The pinkish or flesh-coloured flowers are borne in dense racemes. They appear about a week or two later than those of R. Pseudacacia, and are odourless. There are some interesting forms of hybrid origin, between the common locust and R. viscosa, known as R. dubia, R. ambigua or R. intermedia, more than a century old. The type of this hybrid comes rather near R. Pseudacacia, while a later form, known as R. bella-rosea, much more resembles the other parent. Both are very interesting forms from a horticultural point of view, and are still rare in our gardens. Our picture shows a form of the hybrid almost identical with the typical R. dubia, the flowers being nearly white and somewhat fragrant. All these forms grow as freely as the parents. They are hardy, but have to be propagated by grafting in spring on young seedling stock in the glasshouse.—CAMILLO SCHNEIDER.



THE GRACEFUL AND CLOSELY PACKED FLOWER CLUSTERS OF THE HYBRID LOCUST

UTILITY AND BEAUTY.

A CONTRIBUTOR to these columns recently wrote appreciatively of the beauty of vegetables, praising the jade and ivory of the cauliflower and virile beauty of the carrot, and few people, I think, will dispute their decorative value; but we must admit that it is difficult to employ it, except as a subject for still life, in any satisfying harmony with our surroundings.

On the other hand, there are many plants, lodged firmly in the category of vegetables, which can be used, quite practically, for decoration, both indoors and out, and it is worth recalling them now, when the planting season is upon us and the gaps in our borders threaten correspondingly large holes in our pockets.

The common sage does not often get an opportunity of flowering in the garden, but one has only to see it in great stretches of grey and lavender on the sun-baked hills around the Mediterranean to recognise it as a plant of really high decorative value. It needs a poor, dry soil and a sunny aspect to flower well, and, given these conditions, it makes as brave a show as many of its relatives who have an assured place in the flower border. It associates well with the ochreous yellow of the Jerusalem sage (Phlomis fruticosa), and the two plants may often be seen growing together in Dalmatia.

Chives make an excellent edging plant, giving the effect of a lavender-coloured thrift, and free flowering does not diminish the production of leaves, two or three of which add so much to the value of an omelette or a salad. I believe that a variety which grows wild in Cornwall has deeper coloured flowers and is sometimes listed in catalogues of alpine plants as Allium sibiricum.

Rue is a plant that has fallen steadily out of favour since the Middle Ages, till in these pages it was recently labelled as a poisonous plant and relegated to the company of Atropa Belladonna in the medicinal garden. Yet a few of its leaves finely chopped, mixed with butter and enclosed between slices of bread toasted on one side only, make one of the

Digitized by Google

most delicious and appetising sandwiches imaginable. Even if it had not this virtue, and a singular tonic property for young turkeys, rue would be a valuable garden plant for the delicate design of its scalloped leaves and their glaucous-grey tone which make a perfect background for flowers of a pure pink, such as the old blush monthly rose, either in a vase of cut flowers or in the garden. Perhaps I am prejudiced in its favour, but to me it is a beautiful, though strangely neglected, plant and even its dull yellow flowers are attractive.

The variegated lemon thymes are—as at least one catalogue has thoughtfully pointed out—as useful in the kitchen as their plain relative, and much more decorative.

Herbs are not the only plants that can be translated with advantage from the kitchen garden to the flower border. The decorative value of the globe artichoke has been long, but not very generally recognised. It has the *grandes formes architecturales* beloved of M. Correvon, and the greyness of its leaves shows up the rich violet of its great thistle flowers; it makes an imposing specimen plant, or it may be grown in a bold group with climbing nasturtiums scrambling through it.

We all admire the fruit trees, apple, pear and cherry, in their superb springtime beauty, yet we seldom plant them, as they did in the eighteenth century, with a thought for their decorative value, though we sometimes make the orchard into a garden with daffodils, cowslips and fritillaries in the grass. As a rule it is only when we see an old apple or pear tree in a cottage garden growing above a carpet of spring flowers that its value as a flowering tree really comes home to us.

The fruit of the medlar is not liked by everyone (though there are few who cannot appreciate the excellence of medlar jelly); but the distinct design of the tree, the large leaves which colour brilliantly in the autumn, and the large white flowers, make a singularly beautiful picture, and almost the same may be said for the quince. But the quince grows so slowly that, unless we are lucky enough to obtain the recently introduced Serbian variety, the full advantage of our planting will go to our children and grandchildren.

There are few more brilliant shrubs in autumn than the common barberry (Berberis vulgaris) when its sombre leaves are lit up with bunches of the long, crimson-scarlet berries. It is not often planted nowadays, partly because of the well deserved popularity of the Chinese species and partly, I suppose, because it is suspected of harbouring the wheat-rust fungus. But it was once commonly grown as a fruit tree, and a jelly made from the berries is rather superior to red currant as an accompaniment to jugged hare and roast mutton, while a seedless variety provides in France that excellent but rather tart sweet known as *conserve d'épine-vinette*. It is almost forgotten as a fruit in England, though before the war it sometimes caught the eye in Oxford Market, making a gay patch of colour among the cabbages and onions.—F. A. H.

A BLUE DAISY.

ONE of the great delights of gardening is to grow flowers that are uncommon, interesting and in some odd way attractive, so it was with pleasure that I obtained some years ago the blue daisy, Bellis cœrulescens. This species of the daisy is in no great degree different from the other daisies, except, perhaps, in size, for it is smaller; the flowers do not rise to a greater height than 3ins. and they are a delightful pale blue. Although said to be hardy, we do not find it so in the north here; nevertheless, plants have occasionally passed through a mild winter in the open, but as a rule the cold rains of January seem to cause its gradual disappearance. The plants do not increase very rapidly, but we always put sufficient for our needs in a rude frame and leave the rest to chance; in rich, heavy soil it flowers freely and we recommend it as a little gem for the rock garden.—CLYDESDALE.

PLANTS AND FROST.

IT is really most irritating to garden lovers to be accosted by the man in the street, after an early snap of autumn frost, to be told what delightfully seasonable weather it is. It is a peculiar thing that when one arrives at some sixty summers, one seems to have no further use for "seasonable weather," which in Scotland, at least, means infernally cold weather—doubtless in hot climes it will mean the reverse.

The night of October 15th brought some of that so-called "seasonable stuff," for, the following morning no less than 12 degrees of frost were registered, the thermometer standing at 20 degrees, which, coupled with a brilliant, mocking sunshine, made a garden, which but a few hours before was a brilliant, gay scene of reds, yellows and purple, a sad, miserable, woebegone spectacle. Yet there were a few plants, a very few, still unsubdued by that cold douche, and surely they deserve our admiration. True! Michaelmas daisies, some of the geums and a stray phlox or two, made a half-hearted effort to show they still existed, but their struggles were like those of the bad sailor on a rough sea trying to be merry, a very forced effort; though, doubtless, they will recover, like the bad sailor when he lands, in better weather. Four plants, however, were quite happy, absolutely so, and not in any way upset for all Jack Frost had done during that night, and by lunchtime were all in their glory again. A careful note has been taken of these, with the avowed intention to bring all four together in large masses, so that at least one cheery corner of garden may still exist in the event of a similar occurrence.

The four plants are (well! two of the plants are shrubs, somewhat like the Irishman who had a light, but it was out), Clematis tangutica, Berberis Prattii, Crocus speciosus Aitchisoni and Gentiana sino-ornata. And what a glorious group they are: yellow, red, purple and blue of the finest quality. C. tangutica has charming thick, fleshy, yellow flowers, and bespattered as it is at present with its silvery seed heads, rambling at will over a rough wall is very delightful indeed. One plant has quite accidentally made a charming effect here by clambering among C. montana rubra, the dark foliage of which makes a delightful contrast to the yellow flowers of tangutica.

Berberis Prattii, has, I consider, by far the finest berries of all the berberis. They are so brilliant in colour, so numerous even on very small shrubs, are distasteful to birds, and frost proof. Although B. Wilsonæ makes a good rival, it was to me somewhat surprising that Mr. Hillier in his recent interesting articles on shrubs did not write in more glowing terms of B. Prattii.

Crocus speciosus Aitchisoni holds pride of place in the autumn-flowering crocuses. It is somewhat larger, has more substance and is richer in colour than C. speciosus. Granted it is much dearer; but while speciosus, with a touch of frost is a slimy, ungainly mass, Aitchisoni is smart, upright and ready to blaze open with the slightest encouragement from old Sol, and by noon on the 16th, it was a charming sight. Mice are particularly fond of the bulbs and pheasants are equally as fond of the bloom, so the gardener has not to seek his sorrows with it.

The fourth plant, Gentiana sino-ornata, is one of the very finest autumn alpine plants which it has been my good fortune to acquire, and when it becomes better known will doubtless be seen in every garden of any consequence. It is equally as hardy as G. acaulis and G. verna, and is happy and blooms freely in almost any situation, though it is somewhat of a gourmand and has a decided liking for high living, coupled with a good dash of drink; it seems somehow rather to resent heat, or at least is not very partial to it. I was somewhat surprised by the behaviour of a few plants which I intended to be extra fine. I told my gardener to put them at the foot of a wall looking south, in good loamy soil, though perhaps a little dry, where I hoped they might be exceptionally fine, but to my disappointment they are the most weakly yellow, bilious-looking plants in the garden, and show but little signs of flowering, while a clump in the open border only 12ft. distant is making a glorious display. —FORMAKIN, *Renfrewshire*.

CEANOTHUS.

THE various beautiful shrubs which belong to the genus ceanothus deserve to be much more widely grown than is the case. The species are mostly natives of the North American continent, particularly California, but there is a large number of fine varieties. The colours of the flowers are chiefly blue, but there are white and even rose pink forms. The ceanothus group is divided into two classes by reason of their special methods of flowering. One group develops its flowers in the spring from auxilliary buds on growths matured in the previous summer. The second group bears its flowers in the summer and early autumn from the tips of the current year's growth. These habits call for different methods of treatment which it is most important to note. Most of the spring-flowering kinds are somewhat tender and do best when planted against a wall. Here the branches should be cut back as soon as the flowers fade. The autumn-flowering ceanothus is an altogether hardier plant and any of the species and varieties may be grown in open beds. These should be pruned vigorously, but here the cutting must be carried out in February. The previous year's wood should be cut back to within a few buds of the base, except when it is specially desired to keep any particular branch. In this instance the dead point of the shoot only should be removed. All the ceanothuses can be grown in a well drained loamy soil. Increase is easy by the insertion of cuttings of young shoots in sandy soil in a closed frame during the summer.—S. LEONARD BASTIN.

THE BUTCHER'S BROOM.

IT is always interesting to note the compensations of nature and how every plant is attractive at one particular season of its year. For the most part the common Butcher's Broom is a drab and uninteresting little shrub, whose chief value lies in its shade-loving habit. For a short time earlier in the year the more observant nature lovers enjoyed its lily-like little flowers, which appeared to be stuck on the middle of the spiny leaves. But at the present time the bright scarlet berries, which are almost ridiculously large for the plant, and have taken the place of the flowers on the leaves, flaunt their beauty and need no searching. These vivid berries might almost be likened to miniature oranges set on pigmy leaves and, in the districts where the shrub abounds, provide material for uncommon dinner-table decorations. Although the native shrub thrives best in sandy soils, where the pines also flourish, it can be easily established and will grow well in any thin woodland, where it will enjoy the leafy topsoil. It is interesting to recall that the shrub owes its common name to the fact that at one time butchers made up branches into little brooms for brushing their blocks. That was the day when young shoots of the spindle tree, another bright denizen of our woods in autumn, were exclusively used as meat skewers by butchers. The best chopping blocks were, and mostly still are, made from the wych elm.—A. C. B.

Digitized by Google

THE BIRCHES

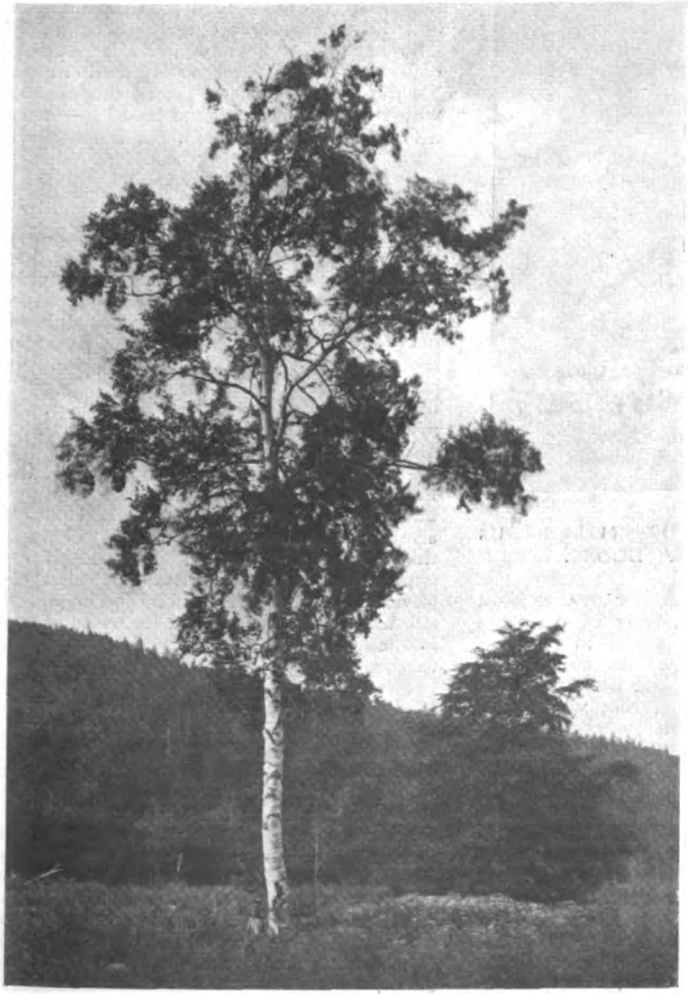
BY E. H. WILSON.

(*Continued from page* 698.)

IN the last article I spoke of the river birch, and this reminded me of B. davurica, which has a similar bark, curled and shaggy, but thicker and deeply fissured into irregular oblong plates that are blackish on the lower part of the trunk of old trees. On the volcanic soils of north Korea, where this birch is so abundant, it forms, together with an aspen (Populus tremula Davidiana), the natural nurse trees of larch. However, it is by no means confined to volcanic soil, and is found west into north China and east into Japan, where it occurs as a rare tree on the Shinano Alps. This Dahurian birch grows from 50ft. to 80ft. tall, and has a short trunk from 5ft. to 10ft. in girth which forks after the manner of its American relative. On trunk and branches the reddish grey bark either peels off or remains in loose untidy masses. The tree grows well in the Arnold Arboretum, but in the British Isles, like other arboreal continental types, it is apt to start into growth early and to suffer from subsequent late frosts. It ought to be a useful tree to associate with larch in the Highlands.

It is passing strange that the foliage of all the birches changes to shades of yellow in the autumn, but in none is the tone richer or purer than in the cherry or black birch (B. lenta). This is a very common tree in the forests of eastern North America, growing from 60ft. to 80ft. tall, with a trunk from 6ft. to 15ft. in girth. The branches are relatively slender, spread horizontally and are pendulous towards the ends, forming an open, narrow bell-shaped crown. The bark is smooth, firm, dark brown almost black, tinged with red beneath, and on old trees furrowed and cracked into thick irregular plates. The black trunks are

B. DAVURICA, THE SHAGGY RIVER BIRCH OF NORTHERN KOREA



THE HANDSOME B. JAPONICA IN NORTH-EASTERN ASIA.

sombre and in strong contrast with the grey trunks of oak and maple, and the white of the canoe and grey birches, among which this tree grows. In autumn its splashes of pure yellow illumine the forests. By fermenting the sugary sap of this tree the birch beer of the Indians and early colonists was obtained, and by distillation is yielded an oil used medicinally.

The Japanese cherry or black birch (B. grossa) very closely approximates to its American relative, but in habit is a less attractive tree. It has similarly aromatic bark, dark, firm and fissured on old trees; but the trunks are apt to divide into two or three massive stems, and the shape of the crown is more open and less shapely. It is common in the mixed forests of Japan, and in Hondo grows to a larger size than any other birch except B. Ermanii. Other names of this species are B. carpinifolia and B. ulmifolia. Like all birches, it varies considerably in shape of leaf and bract and in degree of pubescence, but the colour and character of its bark and its aromatic taste and odour afford ready means of identification in the forests.

The wood of all the red and black birches is valuable, quite a little of it being used in furniture-making, more especially for cutting "mahogany" veneers. The most valuable of all is that of B. Schmidtii, the famous Pak-tal of the Koreans. This has pale brown wood, very much used in Korea for making rollers, mallets and other implements, and exported in quantity to Manchuria and China for making axle-trees and felloes of wheels. This birch seldom exceeds 60ft. in height, and has a short stout trunk clothed with thick dark flaking bark and a broad crown of no particular shape made up of massive branches. The fruit is narrow, cylindrical and erect. This tree is very common on steep cliffs and is especially abundant on the Diamond Mountains, where its clear yellow autumnal tints contribute very largely to the autumn glory of that beautiful region. It crosses to Japan, where it is a rare tree in the Nikko region, a volcanic area. In Korea it loathes volcanic soils, and, so far as I know, is never found growing in them. The Pak-tal is growing fairly well in the Arnold Arboretum, but it needs planting thickly to develop a trunk, for, like B. grossa, it has a strong tendency to start life as a shrub rather than a tree. The wood and bark of the very different B. chinensis is almost identical with that of B. Schmidtii, and the Koreans designate it the lesser Pak-tal. This is always a small tree—indeed, very often a bush, and in Korea is found at low altitudes and on any kind

Digitized by Google

the ordinarily dug soil, prevented air passing through it and frost reaching any portion below the top 4ins. or so. As a youth I was fond of ridging clayey soils, and, as years passed, I was more and more convinced that heavy soils properly ridged did improve during the winter months. Some owners of gardens may object to huge ridges of soil in them; but they should be broad-minded and try some ridging. The ridges should be, approximately, 2ft. high and the same width at the base. Do not break up the lumps, but pile them together; the air will pass through, the soil will never be in a too saturated state, and, if frost comes, it, too will help in the work of pulverisation. In early spring these ridges may be broken and levelled with ease. Splendid beds for seeds and young plants will be available. There will be fewer slugs; they do not like soil ridges.—G.

THE SMITHFIELD CLUB SHOW

WE who are chiefly concerned with gardens and gardening are inclined to consider the great seedsmen, such as Carters of Raynes Park, Dicksons of Chester, Suttons of Reading, Toogoods of Southampton and Webbs of Stourbridge, solely in regard to their horticultural trade. But a visit to the Agricultural Hall, Islington, during the first clear week of December, when the agriculturist goes to see the fat stock and the latest improvements in agricultural machinery, serves to impress the gardener with the magnitude of the business in farm seeds done by such houses as those above named. He quickly realises that equal care and attention are devoted to the strains of pedigree seeds which produce the monster mangolds of wonderful symmetry, to say nothing of the turnips, flat-pol cabbages and the wheat, oats and barley, among the grains.

That size alone does not commend itself to the agricultural seedsman is fully evident from the samples, diagrams and analyses which are on view. Externally the mangolds of similar size have no difference, but it is quickly seen that they may vary considerably in their food value. An example of the variation in value was clearly shown by Messrs. Sutton and Sons. In respect to the sugar content alone their tests proved that roots of different varieties, each weighing 10lb., may show sugar content varying from 6¾oz. to 10¾oz. per root. In their latest strain of sugar beet there was also a considerable variation. Taking roots of equal weights, it is shown that the percentage of sugar ranges from 16 per cent. in the older varieties, to 20 per cent. in the selected strains.

As may be expected, potatoes were an important feature of the horticultural side of the show. In addition to perfect tubers of the sorts in general cultivation, there were less common varieties of considerable merit. Messrs. Carter and Co. had excellent samples of the purple-eyed Catriona. Express for early crops, followed by Advancer, are two good kidney varieties, while their strain of Arran Chief had exceptionally shallow eyes. Ranfurly Red, a pink pebble-shaped tuber, shown by Messrs. Sutton and Sons, was very attractive, as also were Red King and Crimson Beauty. Among the many sorts set out by Messrs. Fidler and Sons, there was a good basket of Edzell Blue, which is flowery and of good flavour when cooked.

The outstanding roots were the immense, but perfectly formed specimens of parsnip Maltese, shown by Messrs. Carter and Co., which it is safe to say have never before been equalled. Webb's Early Kohl Rabi combined attractive appearance with perfection of size and shape, and their standard carrots, of intermediate type, were also admirable. Several exhibitors, notably Messrs. Harrison and Sons and Messrs. E. W. King and Co., had valuable samples of globe and intermediate beet.

Fruits were not quite so largely represented as usual, but Messrs. W. Seabrook and Sons had brilliantly coloured Bismarck, Newton Wonder, Cox's Orange and Rival apples, and Mr. T. A. Scarlett had sturdy three year old busnes of black currant Edina which is said to be resistant to the big bud mite.

CATALOGUES RECEIVED.

Messrs. Carters, Raynes Park, London, S.W.20.—Once more the seed season is with us, and its arrival is heralded with a shoal of catalogues of all sorts and sizes. Every year these brochures seem to show improvement in all directions, and to some extent they stand as testimony to the ever increasing interest which is being taken in all matters pertaining to the garden. Among the first to reach us is that of Messrs. Carters, "Garden and Lawn" for 1926. The high standard of their previous catalogues is fully maintained in the 1926 edition, and the amateur and professional alike will find much to interest him in its pages when he or she sits down to make out the seed order for next year. A wide selection is offered, both in flower and vegetable seeds. The floral section occupies some eighty pages, all of which list up-to-date varieties in the many annual and perennial flowers which can be found to adorn the garden. Included in the lists are numerous novelties for 1926, and to these the amateur should give his attention and consideration. The growing of novelties always adds a certain zest to one's gardening. In the vegetable section all the leading sorts are dealt with and their respective characteristics are clearly set forth. Once again we would draw attention to their new Giant Podded Dwarf Pea, "Giant Stride," which made such a great hit in the vegetable world last year. The reports which have been received from all over the country during the past year testify that the excellent qualities of this pea as set forth by Messrs. Carters are by no means exaggerated. An important section of the catalogue is that devoted to the lawn, in which many grass mixtures are offered, suitable for all types of lawn. Little recommendation is needed in this respect, as Messrs. Carters' name is already sufficiently well known in connection with lawn work. The subject matter is well and clearly arranged, while the illustrations almost overawe it in numbers and excellence of production. The few colour plates which are to be found might have been better executed. They do not present the true appearance of the floral subject illustrated. Still, that is a point of small import in the consideration of the catalogue. It is a manual for all garden lovers. Each and all will find something of interest and help in its pages, and a copy should be procured within the next few weeks, so that the spring work can be tackled promptly in order to give the seeds every chance of growing into fine healthy plants to grace the garden in the year 1926.

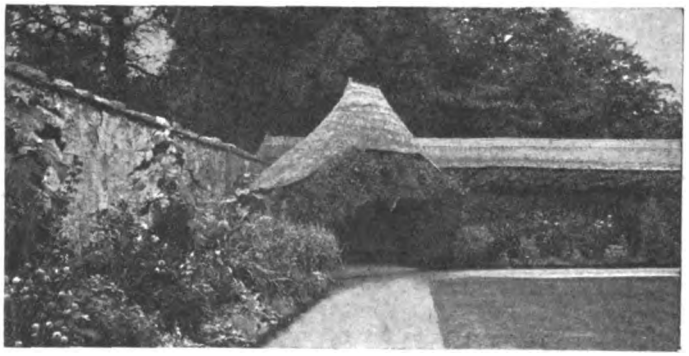
Messrs. Geo. Jackman and Son, Woking Nurseries, Surrey.—Herbaceous and alpine plants. Also a list of ornamental trees and shrubs, together with a very fine selection of hardy clematis.

Messrs. Little and Ballantyne, Carlisle. List of ornamental trees and shrubs, including an extensive list of fruit trees.

Messrs. Keith Luxford and Co., Harlow, Essex. Select list of chrysanthemums and perpetual-flowering carnations.

YOU CAN GIVE NO BETTER GIFT

to your friend, either at home, in the Colonies, or abroad, than a weekly copy of



THE GARDEN

It means 52 remembrances of friendship in the year

If you will ill in the form below, we do the rest.

THE LAST NUMBER OF THE YEAR

AS most readers in the British Isles will receive their copy of THE GARDEN on the day before Christmas, we wish them the compliments of the season. For the next week or so most readers will forget gardening matters or will be storing up energy for immediate work in the garden at the first sign of spring, so let us hope that they will excuse us for quoting a letter that arrived a day or so ago. Our correspondent says: "I wish to congratulate you on your interesting publication, and especially so in respect of the most beautiful and artistic reproduction of the Berried Berberis on the cover of a few weeks ago. The greys, greens, and the bright red berries were admirably rendered. I speak as a printer and so have some knowledge of block printing. I think that week's cover one of the most artistic that I have yet seen THE GARDEN enclosed in, and worth preserving when the time comes to bind up this year's volume. With best wishes for the continued success of THE GARDEN."

Now, that letter is one of the pleasantest Christmas presents for which any editor could wish. It is the habit of many of the general public to consider the Press as a frigid and soulless institution; but I, as a small member of a mighty unit, like appreciation as well as anybody else. I have likes and dislikes the same as any other mortal, and I take the greatest pleasure in feeling that—in the case of THE GARDEN, at any rate—there is a feeling of comradeship between the editorial staff and the readers of the paper.

We hope and believe that the paper is gradually taking a form that is both instructive and interesting to the majority of gardeners. With the present change that is taking place in post-war gardening, we have had to feel our way, the same as anybody else. It has often proved difficult to judge what to include and what to leave out: our judgment has been influenced by our belief that most gardeners are interested not only in ordinary flowers but in an occasional out-of-the-way flower, and not only in the result but in the processes of growing. This is a change from old-time gardening, when the owner of a garden bothered little as long as a sufficient supply of flowers and fruit was produced by his gardener. Many of our readers would help us enormously by sending in constructive criticisms of the paper, for it is by such means that we can keep in closer touch with what gardeners want and like in the way of information. Some old friends of the paper are consistently helpful throughout the year, but we should like every reader to feel that he had a personal interest in the paper. It is natural that some suggestions that have been made we have been unable to carry out for various reasons, but the majority have been acted upon and in many cases have gone a long way towards helping our judgment.

Gardening is divided up into so many classes for which we have to cater that there is bound to be a proportion of the information we give in any individual issue that does not bear directly on the interests of each and every gardener. There is the specialist in a particular genus; there is the gardener who lives for his vegetables or fruit; there is the experimenter; there is the gardener whose only interest is in broad colour effects; there are many other types of gardener. All these have to be thought of when we make up the contents of our paper, and sometimes it is no easy task. E. H. M. C.

TWO RESOLUTIONS FOR THE NEW YEAR

¶ *IF YOU LIKE "THE GARDEN" TELL YOUR FRIENDS ABOUT IT.*

¶ *IF YOU HAVE EVOLVED ANY NEW METHODS OF CULTIVATION OR HAVE ANYTHING OF SPECIAL INTEREST IN YOUR GARDEN, TELL ALL GARDENERS ABOUT IT THROUGH THE COLUMNS OF "THE GARDEN."*

ALSO PLEASE REMEMBER TO MENTION "THE GARDEN" WHEN ANSWERING ADVERTISEMENTS. IT HELPS THE ADVERTISERS AND IT HELPS US.

WAYSIDE ROCK GARDENS

BY HALLIWELL SUTCLIFFE

YOU find them in many a village of the dale. Before the world got busy with what it fancied a new gardening cult, there were humble folk whose cottages had only a strip of turf between the wall and the highway. They could roam at will into woods carpeted with sheets of hyacinths, or through cowslip meadows. The moors were theirs, when heather swept in red and lilac glory from rim to rim of the hot August sky. So were autumn's woods, painted by the master hand. Bare-boughed trees, when the snarl of winter came, had a clear-cut beauty of their own.

They had free range and warren, as the old phrase goes, to satisfy their garden hunger. Yet here and there, up the long dale, one cottager was not content until he had a garden of his own. He cut the strip of turf—the strip that lay between his dwelling and the highway—into sods, and laid them " down-side-up " in a heap.

Then he sought out sundry, thick-thewed cronies, borrowed planks and a horse and cart, and together they brought down gallant rocks to his cottage front—big fellows, with the gales and suns of centuries in their seamed faces.

His friends laughed at him, no doubt, as they helped to lay the stones in place, and saw nothing at the end of their toil but a jumble of naked rock, its spaces filled with soil and lime-stone chips. He let them laugh, and went often and alone into the hills that had furnished him with stone. There he gathered his little store of roots, planted them in his garden strip without delay, and watered them freely. It was simply transferring them from one rock pocket to another, and his view of the matter was that " when they woke up on the morrow they wouldn't know they'd been shifted."

I am sure he put it just that way. Such gardeners have simple hearts, and they think always from the plant's standpoint, as individuals with sensibilities human in their capacity for joy or heart-ache. He did not want his nurslings, stolen from the big hill cradle up above, to pine for home—knowing that plants can die of sorrow, though you feed them with all their bodies need so far as soil and aspect go.

By and by he had his reward. It took time, of course, as all worth-while adventures do; but presently the village folk began " to sit up and take notice." Along the cottage front, nearly the whole year round, blossom painted the hoar, age-old rocks with charm. Snowdrops and aconite first, the only flowers that seemed to be of the garden, not the wilds; but even these he had gathered from a neighbouring spinney. There had been a great house on the site, tradition said. Its memory bloomed in spendthrift wildness every March, when the beech buds above were little and tight and brown, and stormy sunlight glinted through bare branches on that wonderful carpet of white and golden yellow.

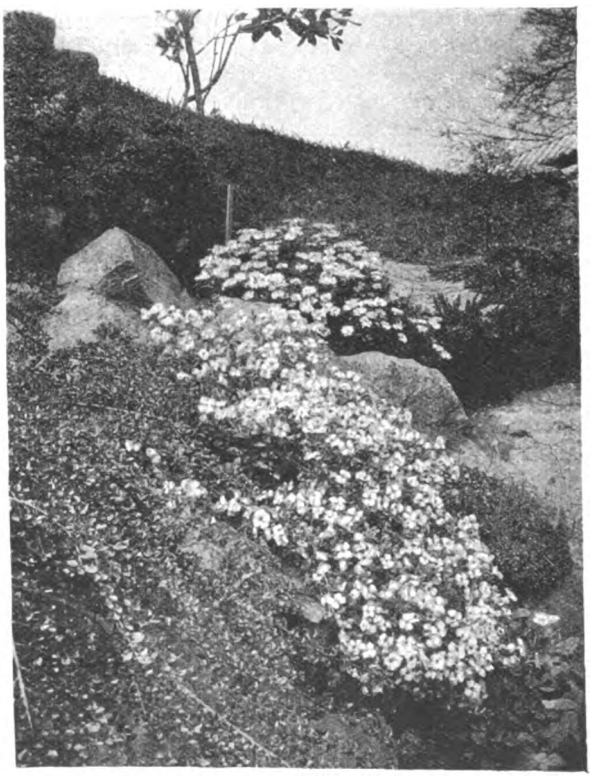
After the snowdrop time, a gracious thing pushed its way up. It had a low, ferny grace of leafage that seemed pleased with mixed weather. If a snow shower laid it low for an hour or two, it rose as if refreshed. Then, as the sunlight had its will again, there was a foam of tenderest mauve-pink, soft as a dream about the grim rock that nurtured it. That, too, the cottage gardener had gleaned from under a clump of hazels near the fabled site of the " Old Hall." Some of the plants, which sophisticated gardeners find hard to name, live on among us; but we do not give away their hiding places. Rare flowers are like a lady's honour, to be kept sacrosanct.

When that mauve splendour ended, the little cottage garden was brave with primroses and the oxlips known in the dale as " Saint John." Then the cowslips came, swaying to every breeze with maiden charm. And after them the bugle-flower, blue as a deep pool reflecting thunder skies.

To tell of that one rock garden is to lose faith in one's bigger spaces, tend them as one will. There are quantities of things we have; but somehow there is missing the completeness of that garden strip, where a cottager went to the hills for his rocks and for the plants that loved them.

There's another garden of this sort—just a strip between the house front and the highway. It is singular, not only for its succession of rich bloom, but for its favoured setting. As you come down the hill from ancient Linton-in-Craven into storied Burnsall, the scene baffles even tried affection's will to praise. First, the quiet church with its lych-gate. Then the grey, Elizabethan school, faultless survival from the spacious days. The raking fells above, and over them the moors that wive the sky.

The garden lies just beyond the school, and after years of intimacy its secrets puzzle me. Aubrietia is there, and London Pride, and friends of the sedum tribe. So is the dale's special garden pet, the pink primrose, and many another proven comrade. To pry into detail is well enough; but the broad effect of this way-side garden eludes explanation. It is, I fancy, that the tender of it has hands that work obedient to the heart, as a great musician plays. Out of the rocks and plants he draws their soul, in tune with his.



A WAYSIDE ROCK GARDEN.

A clown might sit down to the finest organ in the land, and make nothing of it. A casual gardener might build such a wayside strip as Burnsall's, and plant aright—but lacking the mystery known as " gardener's thumb "—and dust of the highway would smother his efforts in drear decay.

In the true sense of a word used lightly nowadays, this garden is a mystery. Dust covers it, whenever the sun licks up the rain from a road much frequented. In wet seasons, the traffic drives mud across its face. It makes the dust and wet a litany of colour, praising heaven. The " gardener's thumb " has planted it.

There is no end to one's memories of these pleasant, way-side challenges to the hurrying everyday. In a fold of the hills, where a grey village nestles, an old woman's cottage stands by the wayside. She had a cobbled strip between her windows and the road, and by removing a stone here and there has made a rock garden of her own devising.

The little, old-world musk flourishes there. Its fragrance, of leaf and flower, used to bring back the most subtle, half-forgotten things—boyhood's memories of old friends, old gardens, ancient trees in whose hollow trunks the starlings built. That was in the days before, from end to end of Britain, the creeping musk lost its fragrance—none knows why, though some wise elders remember a saying that " musk would cry its scent to death one day, in grief for sore trouble coming on the land." Its fragrance will return, they tell us, when the good days are in store again.

In other cobbled pockets grows that ancient of the dale, the dwarf bleeding heart. Feathery leaved, its stems a little

Digitized by Google

drooping under weight of their red-pink blooms, it makes one marvel all afresh how close to nature lore the far-back people were who gave plants their country names. The shape of the flowers, their colour—the slight droop of the stems—all suggest a heart that bleeds with fine comeliness and pride, as for a dear one who died after a worth-while life.

Gentian grows there, too. It does not care that folk less humble than the widow are employing gardeners to compel this special, blue-eyed plant to thrive. They might as well command the east wind to blow, if its mind is not set that way. A maidish plant, capricious seemingly, she knows her heart, for all that. The gardeners she loves are her dear masters; the others see her die, for sheer joy in ending an abhorrent prison time. But when she thrives, as in the widow's cobble garden, you see a radiant charm, secure as deep June skies, not any way to be explained—either by pen or brush. She is simply the maid supremely happy, and the tears on her face at dawn are no more than dew-dreams of the night.

The strange thing about all gardens, big or little, is that they lure one into byways. What one set out to tell of this cobbled wonderland was not its sufficing beguilement and completeness, but the feud it brought to a dale that always had a relish for encounter with "foreigners."

This special zest comes, undoubtedly, from deep sources. We've been harried so abundantly in times past—by Danes from over the sea, by Scots from the far side of Solway river—that instinct resents intrusion, even the most peaceful.

What happened was, that the authorities of the far-off town decreed that the road passing the widow's cottage must be widened. On the other side of the road was a derelict barn, an eyesore and a danger to traffic. So the authorities chose that the cottage garden, innocent and quiet, must be sacrificed instead.

Then the long fight began. We simple country dwellers matched our wits against theirs, and we did as we willed with them, by a process of attrition both subtle and effective.

We won that strip of rock garden for the widow. Not long ago I saw the gentians in full bloom, and there seemed to be frolic humour in their glance.

THE FIRST HARBINGER OF SPRING.

JOHN RICHARD ANDERSON, J.P.

HIS GARDEN DIARY, 1745. A NOTE BY THE HAND OF DION CLAYTON CALTHROP.

(*Continued from page* 312.)

SEPTEMBER.— Comes Betty, one of my maids, a good lass, but ever over hurried, who tells me a gentleman is come to ask for me.

When she has recovered her breath I ask her what manner of gentleman this may be to which she replies, "A very fine gentleman, sir, as fine as ever I saw."

This proves to be my old friend Cornelious Brand, a curious fellow, who spends his days wandering.

I bid the maids to set a room in order at once, telling them Mr. Brand is to have the South room and every attention to his order as it were myself.

(Mem.: Silent men are always the greatest talkers.)

It is nigh on three years since I clapt eyes on Cornelious and here he comes and passes the time of day with me as it were we met but yesterday, and that with my garden in full autumn beauty, but he looks round and does say, but, "Great content," and drinks his bottle of claret sniffing at the bouquet and taking a pinch of snuff now and again to appease his nostrils.

After dinner, at which, please God, he was a hearty trencherman, eating stewed eels, the best part of a duck and twice of good mutton, he opens his mouth after half a bottle of port and tells me he is lately out of France and Italy, having walked like any mendicant.

"Lord, Jack," he says, speaking pat, 'I must give a guinea to your cook, and buss her, if she be comely, for that duck, for I am sick of kickshaws. I want no more of Italian oil or French vinegar for a long time and I trow, Jack, there are more eggs and less meat in France than in all the world. But, Lord, the mountains, man, I am grown to love mountains more than women, both change ever, but the mountains do not talk, both have infinite variety, but one is due to Nature and the other to fashion." (Note: To quote same in company.)

This friend hath a manner of speaking so vigorous that it puts life into a man to hear him, but he do fill my garden so full that it seems the very flowers pale beside him, yet we have many friendly silences withal. He loves big spaces, great trees, large dogs and healthy children and can charm a shy bird to come to him. (Mem.: In reading my chapter in The Book to-night I am minded of David and his great ways. Methinks Cornelious might put a man into the forefront of the battle. On second thoughts—"Judge not and ye shall not be judged.")

(Mem.: To ask Mrs. Heath how to make a Cornish Pasty.)

I had but to put a question here and there to keep the flow of his talk in a straight course, for he would speak of wars and flowers in one breath, but in all I did get the wind of his conversation to blow from the south.

"Lord, man!" he said to me, "Had I not spoke French as do the natives I might not be alive, but I do that and also took my brushes and colours with me and that is a visé with the French, for they conceive an artist to be a legitimate madman. In the South the people who live in the mountains are a simple, God-fearing people and they harboured me well.

"Lord, man! The spring! (Note: I will leave out his divers strange oaths.) And trouts do abound so that any man may have a good meal for the asking and the peasants say God put them in the waters for Friday s eating, which is a pretty thought in these Papists.

"In the pastures through which run these streams, and by the roadside, grow countless flowers, making your heart rejoice in their beauty. Of gentians, not a few, and the mealy primulas standing dainty with their feet in streams, and daffodils and the narcissi so plentiful that men scythe them: the white lily they call Saint Bruno, marvellous beautiful, together with Daphne and the Bears

Digitized by Google

Grape Hyacynth. In such guise the feet of the hills are clothed so that a man may feel not so lonely in face of the great mountains covered with snow and ice, carrying man's thoughts to solitude. You have peace here, Jack, but what a peace is theirs!

"The meat grows at your elbow, the fish at your feet, corn sings in the valley where are coneys and a multitude chickens.

"In Italy, too, they have flowers, but not so richly set, and they eat a good dish of paste of flour with Tomatoes and cheese as good as a man can care for, but the wines are not so good, except one cares for the wine they call Chianti, very palatable!"

Talking and drinking we were till dawn and I none too tired yet, feeling I had travelled far in those hours and could feel the prick of the sun on my eyeballs. So when Cornelious had retired (I helping him to bed, he being merry and singing), I made myself a brew of lime flower water and betook myself into my garden, there to enjoy the solace of early morning and to hear the thrushes sing matins and to smell the flowers come fresh out of their sleep.

December.—Here is snow, very seasonable and plentitude of berries on the holly, which I like muchly to see, though some say it means a hard winter, which is cruel for the poor.

Last night for the first time this year I did have my warming pan in my bed and a fire of wood from the old elm which was blown down in the storm. It is sad, but it did provide me, not only with firewood, but with a good rook pie, many birds being shot by my groom, for which I did upbraid him; yet the pie was good (Mr. Smalley's method to cook a rook pie). Mr. Smalley, a sweet reasonable man and very delicate in all manner of food and drink and says a snipe and a woodcock must but fly through the kitchen and a Teal hung eight days. He told me also the manner in which false marrow may be made: to take fat of salted beef and cut it up very fine and serve with a toast of bread. Excellent good.

A sharper frost that men say has not been known in sixty years, the river frozen solid, and cattle found dead in fields and birds to the very doors of houses for water. In my garden abundance of starlings, tits, thrushes and blackbirds, which is cousin to a thrush, but not so sweet in song to my thinking, and yesternoon two reed warblers and a redstart come to eat of my bread and grain. These little servants of God move me mightily and I do thank God Who made provision for the recesses of our nature so we may rejoice in little things and look in awe at the magnitude of His creation.

To-day comes an old man for years a worker in my water meadows, ten years crippled with the Rheumaticks and now upright and would wish to work again. He took but an old wives' tale that he must sting himself with bees and did so and now all his pains are gone and I did marvel, but there it was.

Thank God for the Cordials I caused to be made last year, so now I have abundance of Elderberry, Cowslip and Ginger Cordials, also Plum, Crab Apple and Damson Cheese. My cook hath also preserved red and white currants in sugar, which make elegant dishes to grace my table.

Seventeenth.—Hear to-day of a matter now laughable, but was like at one time to be nigh tragical. One Coles, a plover netter, essaying to pass over the ice by Hoplode Drove, did fall in and was near to drowning, being full of strong ale, but his dog, seeing the affaire did turn his posterior to his master and by barking showed him how he might use his tail for a rope, so he was saved and the dog none the worse.

(Mem.: To cure a whitlow, an onion very hot bound tight about the place.)

Comes my bailiff to request me to see what he hath fatting for Christmas, and a good sight it was, though in a manner pitiful for the birds and pigs. I have twelve geese, of which I give ten away, as usual, also four pigs, very fat, seven ducks and a few capons.

As God, through my fathers, has given me plenty, it is well to give in plenty, so I bade my cook to make twenty cakes, very rich, for the poor of this parish and to kill three of the pigs to make a feast with a cask of ale. (To give kindling also?)

In my fruit house now a great abundance of apples and many winter pears, together with herbs now well dried. My frames do still yield me a salad and I have good store of potatoes.

Mem.: Mrs. Hornblower hath told me to fry some potatoes in bacon fat and keep them and to warm them when need be for a side dish: also to keep peas in a bottle and preserve them green.

My garden now under a mantle of snow and my bee skeps with old cloth about them, so my bees shall not perish.

Later.—The church choir to visit me with carols of that good King who did look out on the feast of Stephen and many others. Mighty pretty to see and to hear, with lanthorns gleaming on the snow and the cobbler playing on his fiddle.

The year is nigh gone and my garden is trenched; my fruit is now turned in the fruit house, the apples in good order and none bruised or sweating. Of Pears my baking and roasting pears, especially French Wardens, do excel, being covered with straw against the frost. The Bergamot, very good to eat now and full of juice. Even the great frost and snow have not burst my Fountain pipes and only one of my water barrells hath burst its hoops.

Much merriment of Mummers who made the old play for me before the house and then asked in and ale given hot with sops of toast, the Dragon and St. George taking ale together most friendly and singing an old catch older than their father's fathers. Then a bowl of good punch (Sir Andrew Orvell's recipe). We drank to Absent Friends and they did make much of me in a speech spoke by an old man, Giles Orton, very prettily put and with much mirth, so I left him and went to wind my clocks.

THE CULTURE OF CALANTHES

DURING the winter months, especially when the bulk of the chrysanthemums are over, flowers are none too plentiful, and it is at this period when a good batch of calanthes would be found most valuable. They are excellent cut flowers, as they will last for two or three weeks with care and attention, while as decorative plants for the dwelling house they are ideal, particularly if arranged with a few ferns. Moreover, they are easily grown and no one need fail in their culture.

Wonderful progress has been made in the cross-breeding of orchids since the first hybrid appeared in bloom in 1856, but it is remarkable that Calanthe Veitchii, which was raised about the same time is still the most popular and widely grown of the genus. It is derived from the inter-crossing of C. rosea and C. vestita. C. Veitchii possesses a robust constitution, free flowering and the bright rose-coloured blooms on gracefully arching spikes are at their best in mid-winter. A fine pure white calanthe is C. Harrisii, but this hybrid is not quite so common as Veitchii and a little more expensive. Other hybrids are named Bryan, Wm. Murray, and Bella, while the principal species is C. vestita and its several varieties. A late-flowering calanthe is C. Regnierii.

At the present time the calanthes have finished flowering and the bulbs are at rest in a temperature of about 50° Fahr. Both species and hybrids should be re-potted directly they start into growth. The bulbs are turned out of their pots, all the old soil is shaken away, and the roots which are dead are cut back to within an inch or so of the base of the bulb. At this stage the bulbs must be thoroughly cleansed if scale or mealy bug is present, with a sponge and tepid water. Ordinary clean flower pots from 5ins. to 7ins. in diameter are chosen, and these are filled one-third of their depth with drainage material, over which is placed a thin layer of moss to secure a free outlet for water. The rooting medium consists of two-thirds the best fibrous loam, and one-third peat and partly decayed oak or beech leaves, with a little sand or finely crushed crocks added. All the dust or fine particles are removed from the loam and peat, both being used in a lumpy state about the size of a large walnut, while the leaves are rubbed through a ½in. mesh sieve, and afterwards the dust is sifted out, leaving a light, flaky material which many orchids enjoy. The whole is well mixed and placed in a warm shed for several days before it is required.

Some growers pot the bulbs singly, a method to be commended if space is available, otherwise several bulbs can be arranged in a fairly deep pan, 7ins. or 8ins. in diameter.

An average size bulb will need a 5in. or 6in. pot. The compost ought to be made fairly firm and brought to within

Digitized by Google

an inch of the rim of the receptacle, but care must be taken to see that the new shoot is not buried. It should rest on the compost when the new roots will soon enter the soil. When the repotting is completed, stand the plants in a shady part of the cucumber house, stove or warm orchid house, where the minimum temperature is 60° to 65° Fahr. With sun heat these figures can be exceeded and no harm will accrue. For the first few weeks water must be afforded sparingly or the new shoots will decay, but the surroundings are kept moist by occasionally sprinkling water on the floors and stages.

When root action becomes vigorous, and the leaves begin to unfold more water can be applied, and directly the new bulbs are formed weak liquid cow manure may be given once each week with beneficial results. During the growing period a moist, buoyant atmosphere is needed, and a little ventilation should be given whenever the weather is mild. Ventilation is important throughout the summer months, and it is advisable to leave the top ventilators open an inch or so during the night. This will allow any superfluous moisture to escape, and thereby prevent the appearance of the black spot disease. In the early stages of growth shade will be needed from strong sunlight, but when the bulbs are nearly completed the plants can be gradually inured to the full rays of the sun. When the leaves begin to fall less water is required, but the soil must be kept just moist until the spikes begin to open their flowers.

At this stage the plants are arranged in a warm greenhouse where the atmosphere is dry, where the bloom will remain in full beauty for several weeks.

Directly the spikes are cut the bulbs undergo a period of rest of several weeks duration, when no water is given. Place the pots on a shelf away from drips in a house where the temperature does not fall below 50° Fahr. If space is scarce or the pots are wanted, the bulbs may be turned out of their receptacles, the soil removed, and the bulbs arranged close together in boxes with their bases set in silver sand.

Now is a suitable time to purchase calanthe bulbs; they are dormant, need less packing and the cost of carriage is thereby considerably reduced. T. W. BRISCOE.

NOTES OF THE WEEK

A FEW UNCOMMON PLANTS.

THE dasylirions are a race of plants seldom met with outside botanic gardens, but they are well worth a place in gardens where suitable conditions prevail for their growth.

There are several varieties, and all are ornamental. Nicholson describes them as greenhouse evergreens, and in the colder parts of the country and in those gardens which lie low and are naturally wet, they certainly will require indoor treatment. They are natives of Mexico and belong to the order liliaceæ.

An ideal position for dasylirions is on a hot, dry bank or in the crevices of the rockery, where they will get the sharpest drainage during the winter; they will stand several degrees of frost with impunity, always providing their roots are dry. Winter dampness is fatal to them.

D. serratifolium is one of the best and, when established, is very ornamental indeed. The foliage is graceful and similar to a narrow-leaved yucca, indeed the whole plant somewhat resembles a yucca, but the foliage droops gracefully, the tips of the outer leaves touching the ground. Flower spikes 3ft. to 6ft. in height are produced bearing upon their upper half dense panicles of beautiful white flowers. Other good forms are D. Hookeri, with purplish flowers and glaucous foliage; D. glaucophyllum, white flowers and long, narrow leaves, 3ft. to 4ft. in length. Another small group of plants seldom seen, but somewhat hardier and, if anything, more showy, are the aciphyllas, or bayonet plants of New Zealand.

The aciphyllas will flourish in ordinary soil, in sheltered positions in the southern half of England and the favoured districts of Scotland.

A. Colensoi is the variety mostly, though rarely, seen. This will make a grand specimen and will reach 6ft. to 8ft. It has beautiful, erect, bayonet-like foliage, the upper portions being beautifully tinted with rosy shades of pink passing at the tips to flame colour. The flower stem reaches 9ft. to 10ft. and is covered with smaller leaflets and white flowers. Another variety is A. squarrosa. A plant of A. Colensoi seen in full beauty is not easily forgotten.

Still another group, requiring treatment somewhat after that recommended for the dasylirions are the furcræas. Most of the species come from Mexico and a few have proved hardy in dry and sunny positions in southern England and Ireland. A plant of F. longæva flowered in a Plymouth garden last year.

The furcræas are evergreen plants with long and broad pointed foliage not unlike that of some of the yuccas. This, in itself, is pleasing, but the full beauty lies in the towering flower spikes, which in F. longæva has been known to reach the height of 40ft. Truly a magnificent spike. This variety is closely followed by F. gigantea, which will reach a height of 30ft.

Some of the hardiest and at the same time most ornamental are F. cubensis. This variety bears flowers which are of a greenish white and bright green foliage, armed on the edges with prickles. F. elegans makes a spike up to 20ft. and bears flowers, white, tinged green, foliage 4ft. to 6ft. in length, with few or no prickles. F. gigantea: this is as hardy as any, and I consider the most showy variety, it soon becomes established and makes a grand specimen, the flowers are milky white inside and stained green on the outside. Foliage sometimes reaches 6ft. in length and with age the plant forms a thick trunk 3ft. or more in height. F. longæva is altogether the tallest, with greenish white flowers and will also form a trunk some feet in height, crowned with foliage 4ft. to 5ft. in length. There are several other varieties. —J. HILL, *Paignton*.

AN AMATEUR'S TOMATOES.

MANY people are unusually shy of their fine tworks, so, bearing in mind the Editor's request to hear from amateurs, I have taken the opportunity of having the excellent results attained by one of them photographed, for, with an absolute minimum of garden—which, incidentally, only comprises narrow borders around his house—I think his efforts most praiseworthy. He is a Mr. George Tucker of Aldenham, and he has devoted his special efforts to tomato growing, and the accompanying illustration will tell the tale perhaps better than the pen. Early each season he gathers together a number of suitable tubs, cleans and paints them, and, having inserted his plants, he tends these with a cultural skill that every year yields the excellent crop shown. The plants are grown in their tubs, at the foot of the south-west wall of his house. Carefully staked, trained, and top-dressed as required, these plants are really a wonder, and at the time that the photograph was taken, one of the trusses on a yellow-fruited plant carried no fewer than sixteen good fruits, while a red

TOMATO-GROWING IN TUBS.

Digitized by Google

variety had seventeen; on a whole plant we found that on six trusses of a yellow variety there were a total of fifty-four fruits; and a red sort, carrying five trusses, had a burden of forty-eight fruits—figures that speak for themselves. So carefully tended were the plants that, far from showing any sign of exhaustion, they looked in the very pink of condition. This annual effort may well serve as an object lesson to many as to what can be done in the space of a few square feet.—E. BECKETT.

LONICERA SEMPERVIRENS.

THIS species, to my mind, is one of the finest of the genus. We raised it here from seed obtained direct from its home in eastern Canada two years ago.

This year it commenced to bloom in May, and the flowering period has extended from then until the present time. Even now, its lovely coral red flowers are available for cutting. These, unfortunate'y, lack fragrance, but its absence is made up by the brilliant colours of the flowers.

We find it very free in almost any position, although it prefers a moist sunny situation. The flowers are followed by attractive orange berries.

This honeysuckle should find a home in all gardens, if only for its long season of flowers. —R. MOORE, *Thorpe Hall Gardens.*

ANNUALS OF GOOD REPORT.

IN the autumn, as first one and then another blossom disappears from the garden, we are inclined to contemplate those which have served us best. Not the least important in these days are annuals, many of which add considerably to the attraction of the beds and borders. Some, however, are inclined to look upon them as of only secondary importance, well enough, perhaps, in masses, yet never treating them as individual plants; consequently, they are not always able to appraise them at their right value. It would, I think, be interesting to know what are generally regarded as the most useful annuals—hardy or half-hardy—from the point of view of all-round service in the garden, and for cutting. It has always been somewhat of an enigma to me to find that the same kinds of annuals are grown year after year by the same persons, almost leading one to suppose that, for some reason or other, the owners of the gardens are limited in their choice or are conservative in their ideas.

Possibly, if we were asked to name one dozen annuals noted for their all-round usefulness, we might find a difficulty in doing so on the spur of the moment. For the rock garden, for sweet perfume, for bringing colour to the borders, and for cutting for table decoration, I select those (without order of merit) which have given satisfaction: Sweet peas, eschscholtzias, mignonette, larkspurs, calendulas, sweet alyssum (Little Dorrit and Lilac Queen), antirrhinums (treated as annuals), sweet sultans, nigella, statice, Matthiola bicornis and clarkias.—W. F.

CHRYSANTHEMUMS AT OTTAWA.

THE accompanying illustration shows a corner of the Chrysanthemum Show at the Canadian Government Central Experimental Farm, Ottawa, now one of the annual events of the Dominion. Over three hundred of the best varieties (the result of the experimental work of the Horticultural Division) were brought together, and these 3,000 plants shown at their best made a magnificent display which attracted people from far and near. The feature of these exhibitions is the great variation in size of flower, form and colouring. New varieties originated in the Ottawa greenhouses include Lady Byng, J. H. Grisdale, E. S. Archibald and J. R. Booth.—CANADIAN OFFICIAL PRESS BUREAU.

A FINE DISPLAY OF CHRYSANTHEMUMS.

CURIOUS PLANTS.

THE Editor, in a recent number of THE GARDEN, declares his appreciation of succulent plants with a firmness as admirable as it is uncommon. For most people who grow and like these plants are apologetic for their taste, nervously anticipating the criticism "more curious than beautiful" that hovers on the lips of the visitor.

Yet the cacti are often beautiful in their symmetry of design and the graceful ferocity of their armature, and beautiful also in the delicate brilliance of the flowers that sprout so unexpectedly from their stony contours. Even when the succulents have none of these qualities, but have been warped by adversity out of all likeness to a plant till they look like elephants' feet or gallstones or cricket balls, they are still admirable for their singularity and their triumphant adaptation to conditions in which no ordinary plant can live.

These plants, which can thrive in the Kalahari Desert on little soil and less water, must be nearly as thrifty as the lichen which hangs in festoons from the telegraph wires in Rio de Janeiro, and we hope that they will flourish bravely in the Editor's London flat; where, if one may venture a suggestion, they will probably appreciate the violet rays which are given out by certain special types of electric light bulb.

For the gardener in the country there are many plants worth growing which are curious in another way. Not for their strange form, but for their singularity in breaking away from the traditions of their family. A mere departure from the type is not inevitably interesting except to botanists, but many of such plants have acquired a strongly marked individuality which will recommend them to the ordinary gardener.

There is a plantain which has strayed up into the mountains, or been stranded there, and become as white and woolly and aristocratic as any of the high alpines in whose company it sometimes worthily finds itself in the rock garden. Farrer describes a dandelion which grows "beside the glaciers of Kasbek" and there produces flowers of an intense violet purple. It would make an interesting companion for the plantain, if we could get it, though one may doubt whether a dandelion, however purple, could be really beautiful, for the habit of the flower is as dowdy as the elfin architecture of the seed heads is refined.

The common dock is a statuesque plant and the spires of russet seeds are beautiful in the autumn pastures, but I have never had the courage to experiment with it in the garden, though its relative, Rumex flexuosus, has an undisputed place there. This is not a showy plant; indeed, it is difficult to see it at all except at close quarters, but the snuff-brown of its dull, wrinkled leaves is unlike any other colour in the garden. It is sometimes called the "drunken dock," because its stems lurch about in uncertain zig-zags and often flop prostrate on the ground. It is almost unnecessary to say that this oddity comes from the Antipodes.

From the same land of inversion comes Hymenanthera crassifolia, a relative of the violet which grows into a small woody bush; this again is not a showy plant, but it calls attention to itself by having piebald berries.

The butcher's broom does not invite attention in any way and seldom gets it, living dourly under the shade and drip of trees, where, owing to a Calvinistic habit of segregating the male and female flowers to separate plants, it often forms celibate colonies and fails to produce the blood-red berries which are its sole attraction to the eye. Yet it belongs to the Liliaceæ, a family rarely given to self-effacement. For the botanist it has the distinction of being the only native monocotyledon with a woody stem; and even the casual observer may be interested by the odd position of its minute greenish flowers, which seem to be stuck on to the middle of the leaves, though the botanist will explain that the butcher's broom has no leaves but only flattened branches which do duty for them.

There is a myrtle that has become so prostrate by living in the wind-swept Falkland Islands that it looks like a woody little thyme and is quite hardy in England.

There are many other plants which have struck out a line of their own: Aquilegia viridiflora has the fantastic grace typical of all the columbines, and its strange tones of green and chocolate are a development not altogether unexpected from the family's

Digitized by Google

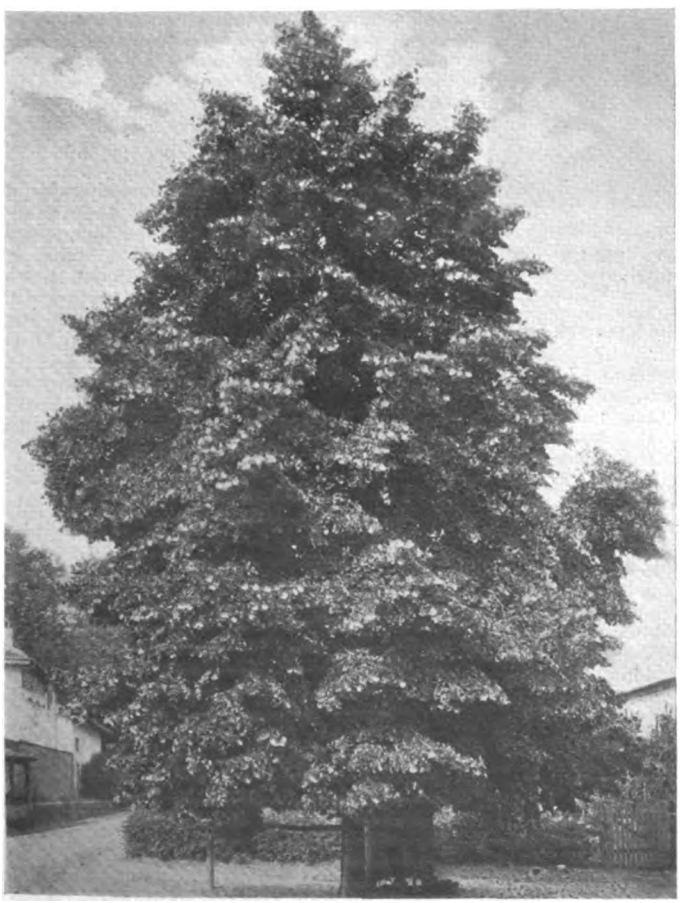
slight tendency to sombre colouring, but it is quite individual and peculiar in a strong, sweet scent that faintly recalls the heavy fragrance of Daphne Mezereum. And there are giant groundsels like Senecio Clivorum, grey groundsels like S. Grayii, pigmy gunneras, pink gentians, violet forget-me-nots and yellow campanulas. From all of which the ordinary gardener will probably turn, with a certain relief, to the frank and unsurprising charm of his sweet peas and lupins—from which, it can be hoped with perfect confidence, his affections will never be permanently seduced.—F. A. H.

AN INTERESTING HYBRID LINDEN.

AMONG the forms of tilia which I have seen from time to time at the Simon-Louis Frères nurseries, near Metz, was one which was called T. orbicularis. It had been raised from a seed of the so-called pendent silver lime, T. petiolaris. The tree, although it much resembles T. petiolaris, is said to be a hybrid between pedicellaris and the Crimean linden, T. euchlora. The leaves of the hybrid are not so silvery beneath and much more lustrous green on the upper surface. This and the whole aspect of the tree suggest the influence of euchlora. T. orbicularis is certainly a fine tree and ought to be more often seen in our gardens.

Both of its parents are valuable trees, and of great interest from the point of view of their real origin. The Crimean linden is regarded as a hybrid of the Caucasian linden, T. caucasia, or as it is called now, T. rubra, a widely spread Oriental species, and our common small-leaved lime. The true T. rubra, which apparently is a rather variable species known under various names, as corinthiaca and multiflora, seems not to be in cultivation at all. T. euchlora probably originated as a spontaneous hybrid somewhere in Trans-Caucasia or the Caucasus, and was introduced from this region about sixty years ago. It goes under the name T. dasystyla, but the true dasystyla is a variety of rubra and may be the real parent of euchlora. This is certainly one of the best linden trees used on the Continent, but, according to Bean, quite uncommon in Great Britain.

The other parent of orbicularis, the pendent silver linden, T. petiolaris, is a rather strange species too. It is closely allied to the white lime, T. tomentosa or T. argentea, often also called T. alba. This is a well known, handsome tree from eastern Europe and Asia Minor. In some parts of southern Hungaria and the Balkans it is apparently mixed with or partly represented by T. petiolaris, known also as tomentosa var. petiolaris or alba pendula. While T. tomentosa has a rather stiff, pyramidal habit, at least on younger plants, the branches are somewhat pendulous, but not really weeping, and the tree forms a more round topped head. Both lindens have silvery white leaves, and are of great beauty.



THE HANDSOME HYBRID LIME, TILIA ORBICULARIS

Another interesting hybrid of which one of the two species is a parent, is T. spectabilis, apparently a cross with T. americana. It originated together with S. Moltkei, which is very similar at Spaeth's nursery at Baumschulenweg, near Berlin, and a similar form was raised from seed of petiolaris at the Arnold Arboretum.—CAMILLO SCHNEIDER.

MAGNOLIA ACUMINATA IN ALL ITS BEAUTY OF FLOWER.

THE CUCUMBER TREE.

AMONG the various kinds of magnolias that are grown in central Europe, there are only two species that form large trees. One is the Japanese M. hypoleuca (representing the true M. obovata of Thunberg, a name hitherto wrongly used for M. liliiflora or M. purpurea, or even for M. denudata), and the other, the North American M. acuminata. This last species was introduced to Europe nearly two hundred years ago, and there are some very fine old trees in different places on the Continent, as well as in Great Britain. When I was staying in Vienna, I often visited the well known park of the Duchess of Ratibor at Grafenegg. Here I took the picture of part of a richly flowering tree of M. acuminata, which measured about 60ft. in height. The flowers which appear late in May or in the beginning of June, are not very conspicuous, but looked at at a distance are quite charming, of a somewhat glaucous greenish yellow. They are slightly fragrant. Its common name, cucumber tree, is in allusion to the shape of the fruits, which, however, only remotely resemble a small cucumber, and are dark red when ripe. According to Britton it inhabits the slopes and borders of streams from western New York and southern Ontario to Illinois, Arkansas, West Virginia, Georgia and northern Mississippi, sometimes forming forests. In central Europe it does not do so well as the Japanese hypoleuca, but it is a good tree for the park.

M. hypoleuca was not introduced until the middle of the 'eighties of last century and consequently there are not many large specimens throughout the country. Years ago it was supposed to be quite a valuable forest tree in central Europe, but some of the foresters, like H. Mayr, apparently expected too much of it. As a park tree it should be planted much more, and Mr. Bean is right in calling it one of the most striking and beautiful of all northern trees both in leaf and in flower. The latter appear even somewhat later than those of M. acuminata; they are large, cup-shaped, measuring up to 6ins. across. The purple stamens and golden anthers look extremely fine between the soft, creamy white petals, and the scent is very strong and agreeable.

There are even finer late-flowering magnolias, like M. Watsonii, but they are by no means as hardy as hypoleuca. This species is used as stock in Japan, and M. acuminata is likewise a good stock. Both like a good, deep, well drained, but not dry soil. No magnolia should be planted in poor ground, but if this has sufficient moisture and is enriched with fresh loam, the tree thrives well.—C. S.

THE LAST SHOW OF THE YEAR

THE Royal Horticultural Society held its last fortnightly meeting for the year on December 15th last, when there was a small but fairly representative collection of floral exhibits, considering the time of the year and the hard weather conditions. A touch of colour here and there was provided by the chrysanthemums and cyclamen, supported by the darker tones of rock garden shrubs. Garden sundries, however, were again the principal feature, and these most certainly make up in interest what perhaps they lack in appearance and attraction. During these days, when gardening duties are at their ebb, the gardener should make himself thoroughly familiar with all the various items which go towards making work in the garden a real pleasure instead of a toil. It will be to his advantage later on.

Not so long ago we congratulated Mr. Edwin Beckett, gardener to the Hon. Vicary Gibbs of Aldenham, on an exhibit of berried shrubs which he staged at the Hall. Again we must do so for his fine collection of shrubs as they appear in the garden in winter. Bereft of their summery cloak of foliage, many of our shrubs, especially those introductions from North America and eastern Asia, are of outstanding beauty. Their grace of line and beauty of colour have only to be seen to be appreciated. In the exhibit, which was admirably arranged, were to be seen many representatives of the willow family, such species as S. vitellina britzensis, with its long, deep blood red, whip-like branches; and the Babylonian willow, with its slender dull yellow stems, were prominent. The brilliantly coloured dogwoods were there in variety and served to show to the uninitiated their value as decorative subjects in the garden at this time of the year. The bronzy red hues of the many berberis species were also to be seen and considerably added to the appearance of the stand. Other interesting inclusions were Philadelphus coronarius, whose beauty in winter is rarely seen; the curiously twisted Corylus Avellana contorta; the spiny Ægle sepiaria; Tilia platyphyllos, with its characteristic symmetrical glowing dull red stems bearing closely adpressed polished buds of the same hue; the knotted bamboo-like stems of Polygonum polystachium; and last, but by no means least, many varieties and species of the Rubus family, with their pure white stems, as if they had been severely frosted. As well as being an exhibit of the utmost attraction, its chief merit lay in its educational value, as all shrub-lovers who saw it no doubt realised.

Chrysanthemums and carnations were again the chief floral exhibits at the Show. Particularly fresh and of good form were the chrysanthemums shown by Mr. A. G. Vinten. Some fine single varieties, such as Harmony, Bronze Molly, Mrs. W. E. Cadlow, Kathleen May and Robert Collins were included in his well arranged exhibit. Two good new singles, also shown by this grower, were Eleanor and Challenger. Mahogony, an incurved Japanese variety of uncommon colouring, Favourite and Golden Butterfly were also noticeable. Messrs. Keith Luxford had a small exhibit of chrysanthemums, the best varieties being J. Barnell and Mary Morris. Messrs. Sutton and Sons again showed seedling chrysanthemums in all colours. Chrysanthemums were also exhibited by Mr. W. Brown and Mr. A. Young.

Large groups of carnations were arranged by Messrs. Stuart Low and Co. and Mr. C. Engelmann. The latter firm showed many varieties, including Rouge, Red Laddie, Nero and Improved Ward. Several new carnations were noted on the stand of Messrs. Stuart Low and among them were Sybil and Mary Pearson. Fine blooms of Orange Sunstar, Lady Hindlip, Sheila Greer and Mrs. Hamilton Fellows were most attractive. Messrs. Allwood Bros. exhibited Allwoodii and perpetual-flowering carnations.

All good alpine plants are, rather enviably, dormant in December, but the rock garden need not be without interest even in the depth of winter, as Messrs. Maxwell and Beale showed with a garden of winter flowering heathers, mostly varieties of Erica carnea, whose scorched pink is more telling against the snow than in the smoky light of Vincent Square. Behind them was a wood of dwarf conifers and a dwarf deciduous barberry, dyed scarlet by the frost.

Messrs. F. G. Wood of Ashtead showed their well known miniature rock gardens for the table, 6in. mountains clothed with silver saxifrage and bronze stonecrops—tempting Christmas presents.

THE SEMI-DROOPING BELLS OF LACHENALIA BOUNDII.

Among the other exhibits were the following:

FRUIT.—Messrs. Bunyard and Co.

ORCHIDS.—Messrs. Cowan and Co., Sanders, Stuart Low and Co., and Captain Drummond.

SHRUBS.—Messrs. John Klinkert and Wilson and Agar.

MISCELLANEOUS PLANTS.—Cyclamen, Mr. A. Shambrook; foliage plants, Messrs L. R. Russell and Co.; gesneria hybrids, Lady Mond; hardy plants, Misses. K. and E. Hopkins; miniature garden, Miss G. Howse.

ARTISTS.—Misses E. Andrews, A. Aumonier, M. Broom, H. Parry Okeden, W. A. Raab, H. Spenser, M. M. Townsend, W. Walker, E. Whitelegg and A. F. Wilkinson.

NEW AND RARE PLANTS.

AWARDS OF MERIT.

LACHENALIA BOUNDII.—This form, a cross between L. pendula and L. rubida, represents a new break in lachenalias by flowering at Christmas-time, and as such will undoubtedly prove a great acquisition as a florists' flower. It stands more or less midway between its two parents as regards its characteristics It is robust in habit, and the flowering stems vary from about 8–12ins. in height. The flowers, of a delicate warm red colour softened by a trace of yellow with greenish tips, are drooping or pendulous, at least the lower ones. Shown by Messrs. Bound and Son, Redhill.

CARNATION MARY PEARSON.—The medium-sized blooms of this variety, borne on fairly stiff stems, are of a peculiar shade which might be best described as puce-coloured. The flowers have a delicious fragrance which will sway many in its favour. Shown by Messrs. Stuart Low and Co.

CARNATION SIR ALFRED MOND.—The medium-sized and well shaped blooms of this variety are of a glowing scarlet colour, and are well carried on long upright stems. It should prove admirable as an exhibition variety. Shown by Lady Mond, Melchet Court.

CHRYSANTHEMUM OMEGA.—A medium sized Japanese incurved variety of a light yellow to bronzy hue. The colour is good, but the shape of the blooms shown was not quite perfect. Shown by Mr. H. Shoesmith.

CHRYSANTHEMUM BIANCA.—An excellent variety of a pleasant light ruddy tone with a yellow reverse to the florets. The blooms are flattish and medium in size. Shown by Messrs. Cragg, Harrison and Cragg.

CHRYSANTHEMUM PHRYNE.—This variety should win its spurs as a market flower. The blooms are compact, firm in texture and of medium size. The colour is delicate pure pink and rather attractive. Shown by Messrs. Cragg, Harrison and Cragg.

CHRYSANTHEMUM ZENITH.—This is a large single variety, the blooms being about 3½ins. across. The ray florets are of a bright brick red tone fading to a sulphur yellow towards the cushion, which itself is of a dull yellow. Although striking in colour, it is not exactly attractive. Shown by Messrs. Keith Luxford, Harlow.

ORCHIDS.

AWARDS OF MERIT.

SCUTICARIA STEELII.—The handsomest of the scuticarias as regards the flowers, and interesting on account of the cylindrical, fleshy leaves about 3ft. in length, which are quite pendulous. The flowers are nearly 3ins. in diameter, light yellow, spotted with red-brown, the fleshy crest of the labellum orange-yellow. It was introduced from Demerara in 1836 by Mr. M. Steele, and was subsequently found by the Brothers Schomburgk during their exploration of British Guiana, 1840-44. The present example bore a couple of flowers, larger and finer than the usual type. Shown by Sir Herbert S. Leon, Bt., Bletchley Park, Bucks.

CYPRIPEDIUM THE PRINCESS (Alcibiades × Alcineda).—A distinct flower of large size, in which the dorsal sepal is greenish, with a broad white zone on the apical region, and with small dark spotting evenly distributed over the whole segment; petals yellowish, tinged with mahogany and veined with red-brown; labellum yellowish, stained with mahogany-red on the front area. Shown by Messrs. Armstrong and Brown, Tunbridge Wells.

CYPRIPEDIUM CARDINAL MERCIER.—Full parentage unrecorded, but a hybrid of C. Lathamianum. The broadly formed dorsal sepal has the greater part of its area flushed with crimson-purple, the broad petals deep-yellow, almost covered with red-brown and some venation of a darker colour. The whole flower presents a glossy appearance. Shown by Messrs. Armstrong and Brown, Tunbridge Wells.

CORRESPONDENCE

TREATMENT OF DIERAMAS.

SIR,—I was much interested in the article on Dierama pulcherrima in a recent issue of THE GARDEN. Could any of your correspondents tell me their experience of growing this plant? Does it do best and flower more quickly from seed or from transplanted seedlings? What soil and situation would be best suited to it?—M. S. E., *Cirencester*.

DECORATION OF GARDEN PATHS.

SIR,—In the issue of THE GARDEN of December 12th may I suggest that the photograph of some garden "steps" on page 697 was mis-titled. Should not the title to this photograph have been "The Step Garden," and ought there not to have been a notice above and below intimating that visitors are requested not to use this "step-way" as it is a garden and not "steps" in the ordinary sense? The titling of these "steps" seems to me rather departing from the teaching of your valuable contemporary *Country Life*.—E. H.

NERINE BOWDENI.

SIR,—In reply to "R. H.'s" enquiry (page 707), Nerine Bowdeni flowered here this year with its accustomed freedom in the open during September and October, continuing until stopped by 10° of frost early in November, whereby many unopened flower-buds were destroyed. I suppose one ought to know who was or is Mr. Bowden, but I do not. He is distinguished by having his name associated with one of the loveliest of the amaryllis family.—HERBERT MAXWELL, *Monreith*.

HOLLIES AND MANURE.

SIR,—I have a Silver Queen holly which has been for the best part of a century growing in full sun. For years small bits have been taken from it for our Christmas decorations, and "the enemy" has taken liberally from it also, the result being the dwarf plant has never made a really good growth. About two years ago I had it well mulched with rich manure, and in a few months it responded by throwing up a vigorous growth, now about 10ft. high. This has been a satisfactory surprise to me.—J. HILL POE, *Nenagh*.

ERITRICHIUM NANUM.

SIR,—Referring to the subject of Eritrichium nanum in your correspondence columns, November 28th, page 676, signed A. Gavin Jones, it is with great disappointment that one reads of such a gem as Eritrichium nanum being described in colour as blue, sometimes running into dull pink. Up to the present I had, personally, never dreamt that eritrichium could do such a thing, so different from its universal reputation, of being one of the loveliest of alpines and of the most brilliant azure blue. I have never been fortunate enough to make the plant's acquaintance in its native haunts, but have, nevertheless, enjoyed seeing several plants in flower in captivity; but have never seen them anything but a wonderful blue. Even tiny, puny, half-dead specimens have yielded their real beauty of colour. These, at least, would have been the likeliest not to have gained their utmost brilliancy. Again, why have not our most prominent and experienced authors on the subject put us up to it before. Each book of reference describes the colour as being azure blue, but not the slightest mention of a "dull pink"; in fact, M. Correvon says that the plants when in flower are an unbroken mass of blue. It would be very interesting indeed to hear if other people have noticed a variation in eritrichium's colour. If this is general, why then attempt to grow the plant, as I daresay the sight of its almost unrivalled blossoms are the point of value the plant possesses; but no doubt many of the specialists in alpines grow it because it "requires growing," and it is, no doubt, something to be proud of when one can say they have a choice well established plant of Eritrichium nanum in flower. The descriptions of the plant in your issue lead one to wonder was it really eritrichium at all that the author saw. Was it not a dwarf myosotis of some kind, as these do so definitely vary between the shades of blue and pink. The illustration also does not show very clearly that it is the true eritrichium.—F. BARKER.

MULCHING.

SIR,—Most gardeners will agree with your correspondent, page 691, as to the injurious effects of heavy, dense mulches, under which the soil apparently becomes poisonous to root action, because of non-aeration. Vine borders, raspberry and rose beds are often covered thickly with farmyard manure, and in some cases this is left unstirred or unmoved for the greater part of the season. It is little wonder, then, that the grapes "shank" and the raspberries refuse to make satisfactory growth, and many rose plants die out entirely. But do not let us go from one extreme to the other. I am sure that a good cultivator like Mr. Coutts would not wish some of our amateur friends to think that a mere sprinkling would have much value as a mulch. On the other hand, his advice may be regarded as sound when he says it should not exceed 3ins. in thickness. Provided there is enough of it, a greater depth is not of so much consequence, but it is necessary that it should not lie sodden and inert. In natural woods rhododendrons are often mulched by wind-driven leaves to a depth of 12ins., apparently with much benefit to the plants, but the mulch is being constantly turned over; blackbirds and thrushes are adepts at the business. The advice to stir the soil several inches deep with a digging fork before applying the mulch is good for most plants, but many rhododendrons have their feeding roots in the 3ins. of soil nearest the surface, and they might be considerably injured by the upheaval.

If the soil is not already filled with rootlets, every endeavour should be made to carry out the advice given in the last two paragraphs, *viz.*, to keep the surface stirred to a depth of 3ins. all the summer. The novice, unfortunately, begins this work too late, when the surface has become hard, and is soon discouraged at the impossibility of the task. Wherever a tilth is necessary, the soil should be forked to a depth of 3ins. at least in winter, carefully burying all annual weeds. Pulverised by rain and frost it will later be in such a condition that the Dutch hoe or other cultivator can be used with advantage before it becomes hard. Once a good tilth is obtained and kept, its value can hardly be over-estimated. It is not only a protective covering against drought, but the action of sun and air greatly improves the soil for the next crop.—J. COMBER, *Nymans Gardens*.

VOLES AND FIELD MICE.

SIR,—The destruction wrought by these pests in rock garden, border and woodland has been so great, especially during the past year, that I am wondering if any reader of THE GARDEN has discovered anything by which their numbers can be reduced. Few rodents are more easily caught by nipper traps baited with a little bacon fat, or merely placed in the runs, but this means becomes wholly impracticable when the pests come in battalions, and it involves the death or suffering of birds. One is also aware of the sunken pickle jar or biscuit tin (so suavely recommended the other day by a prominent daily paper), but imagine sinking biscuit tins in a rock garden! Further, I have yet to meet the mouse which is fool enough to leap into any pit of that sort. Poison one has a natural disinclination to use, lest birds and cats (which would be liable to eat the poisoned corpses), are also destroyed, but it appears to me that the only hope of release from these enemies lies in that direction. Viruses, I am assured, are not altogether satisfactory and they are said to involve some of the risks of poisons.

When I say that large groups of shrubs, such as brooms, 8ft. high, have been destroyed by barking, that colonies of the dwarfer rhododendrons have had every bud nipped off, that the pests have done the same for a Clematis montana covering a large wall, that herbaceous plants are mown down, as if from sheer lust, and that autumn berries are cleared away far more speedily than was ever done by birds, sympathetic readers may perhaps imagine the sort of plague we are up against. I have tapped every imaginable source of information concerning remedies, from the experts of the Ministry of Agriculture down to the village idiot, and am as far off salvation as ever. What has the R.H.S. to offer the many Fellows who must be afflicted as I am? Would not a course of trials in vole and field mouse destruction prove to be an interesting and helpful diversion from, or in conjunction with, the antirrhinums and pansy beds. Slugs and snails have been accorded a good deal of consideration of late, and this has been of incalculable service to thousands. I feel sure that practically conducted experiments directed towards the extirpation of these accursed mice would be welcomed hardly less keenly.—A. T. J., *N. Wales*.

NOMENCLATURE IN NOVI BELGII AND NOVÆ-ANGLIÆ MICHAELMAS DAISIES.

SIR,—I find I have unknowingly perpetrated two "howlers" in the names of Michaelmas daisies in my November articles. In both cases the varieties are named after people. As in the case of letters and the Post Office, I often think how wonderful it is that so few go wrong, so with personal names given to plants the marvel is that so many keep right when they change hands time after time. Unfortunately, errors are very difficult to eradicate. Bulb dealers galore will persist in offering William *Copeland* Darwin Tulip, whereas it is William *Copland*, an old Dutch gardener known to the elder Krelage. While as for the changes that are rung on the Tomasinianus part of Crocus Tomasinianus it would almost take a Senior Wrangler to calculate them.

Is it too late in the case of these Michaelmas daisies to get the names put right? Both are excellent varieties, and, for the sake of the gardening public, and also that honour may be given to whom honour is due—that is, to Mr. W. B. Child, the head-gardener at Purple Beeches, Cobham, who raised them—I am asking the Editor if he will kindly insert this note.

*** "Rev. Nunn" should be Rev. Charles Lunn, who in human form is a clergyman near Rugby, and in asters is one of the very best Michaelmas daisy blues we possess. Oddly enough, there was a Charles Nunn who was a clergyman in Cheshire, so the wrong name might have been the right one.

Digitized by Google

The other variety is a Novæ-Angliæ, and I refer to it as Miss Kate Broomhead, whereas the lady's name after whom it is named is Kate Bloomfield. This is an exceedingly fine variety, sharing with Barr's Pink the the pleasing virtue of having flowers which remain open when cut and also on dull days when King Sol hides his face, and which, in addition, display a much brighter shade of rose.—JOSEPH JACOB.

APPLE BLOSSOM WEEVIL.

SIR,—I should be grateful for any advice on the subject of the above pest. Our orchard has now been infested for four years in spite of spraying with the usual winter caustic washes, orchard sprays and, early in June, with arsenate of lead. The trees, to all outward appearance, are in the best of health, good runner growth, clean foliage and plenty of fruit buds formed; but I begin to despair of ever seeing a blossom open or a fruit develop. The stems of the blossoms appear to be eaten through just as the buds are unfurling. When does the weevil lay its eggs in the buds, and would arsenate of lead at that moment cure the trouble?—F. DU CANE, *Maldon*.

ANTHOLYZA PANICULATA.

SIR,—This South African plant is well worthy of the encomium passed on it by Mr. Arnott (page 683), but I think it is better for woodland or wild garden than for the flower border. The brief flowering season, brilliant though it be, is scant compensation for the amount of room claimed for developing the broad blades of foliage. But it is the very thing for lighting up the margin of a woodland glade in late summer, and it possesses some property which protects it from rabbits. They leave it severely alone, just as they do montbretia, which is somewhat remarkable, seeing that both these plants belong to the iris family, whereof many genera are eagerly devoured—all kinds of crocus, for instance.—HERBERT MAXWELL, *Monreith*.

CROPPING A KITCHEN GARDEN.

SIR,—Writing in THE GARDEN of November 28th, "G. I." explained the value of rotation of cropping and successional cropping.

The following successions I have carried out with great success. Ground which had been occupied by Brussels sprouts was marked out and trenched for celery in the spring. Lettuce was grown on the ridges and cleared off before the celery required earthing up.

The following spring the positions of the celery trenches were marked, the ground levelled and a light dressing of dung forked in. Peas (main-crop) were grown on top of the old celery trenches, where they had a good depth of rich soil to root into. Between the peas summer spinach was grown, and in June broccoli were planted out as the spinach and other quick catch crops were cleared.

The treading of the ground in attending to the peas, etc., had made the soil quite firm and in fine condition for the broccoli. I may mention here that by planting early in firm ground we secured sturdy plants which stood the winter without being injured.

The next spring the ground was well dug and manured for main-crop potatoes, and so was enriched and well worked for succeeding crops.

When lifting early potatoes it is usual in many gardens to start at one end of the plot and clear the whole of the ground as one proceeds. In preference to this system I recommend lifting every other row first, thus clearing a space for cauliflowers, etc. This is far preferable to planting between the rows before the potatoes are lifted, as the young plants get more air and are not so likely to be checked as when planted between potatoes—often set closely—and disturbed by the process of harvesting the tubers.

One more point—especially for amateurs—is the drawing up of a cropping plan for next year. One may think this entirely unnecessary, but after watching various allotment gardens for some years I have come to the conclusion that if a cropping plan were drawn up, after careful consideration, fewer mistakes of overcrowding would be made.

Such mistakes as potatoes and runner beans being planted within 12ins. of each other would surely not be made if one sat down and thought out the plan on some quiet winter evening.—N. D. H.

PYROLAS.

SIR,—With reference to the article on "Alpine Bogs," by A. Gavin Jones on page 655 of a recent issue of THE GARDEN and the mention therein as to the impossibility of making the different varieties of pyrola at home in our gardens, I thought it might be of interest to him and to other faint-hearts to hear of the success attained in the cultivation of these charming plants in the garden of a near-by friend. Pyrola rotundifolia and P. secunda are growing in splendid mats, a foot or more across, and several other varieties (including P. incarnata and the allied Chimaphila) are equally happy. They are planted in only partial shade in leaf-mould pockets in a sandstone rock wall. This is not an isolated instance, as I am aware of other cases where varieties of pyrola are perfectly content in their garden home, and do not receive an undue amount of attention.—W. INGWERSEN, JUN., *Sussex*.

BOTANY FOR THE BEGINNER—III

THE ROOT.

IN the previous articles we have discussed the plant cell and the green leaf, and have recognised something of their structure and general utility in the life of the plant. But, according to our definition of a plant, which is composed of leaf, stem and root, the latter two structures still remain to be dealt with. These two organs can be treated in sequence, as they work more or less together, and for the present we will consider the root.

One of the charms of gardening undoubtedly lies in all the mysteries which surround the germination of what is to all appearance a little, lifeless body, called the seed, into a vigorous plant, which may be either a weed of the hedgerows or a monarch of the forest. In the changes which are involved, various organs gradually manifest themselves, assuming their cloak of individuality when they then begin to carry out their respective functions. The first organ to burst from the seed coat and make its *début* in the general scheme of things is a small whitish structure to which the name radicle, or first root, is given. This, every gardener who has watched the change from an ordinary garden pea into a tiny seedling will have witnessed. The radicle, if uninjured, commences to grow downward into the soil, mainly acting under the stimulus of gravity but also to avoid light and in search of moisture and food.

As this little structure develops and grows at the expense of food material stored up in the seed, it increases in length, and this increased length is the result of the division of cells in a special area of the root. As in the leaf, we have an early specialisation of certain cells to fulfil certain functions. This active and growing tissue is not situated, as perhaps might be expected, at the extreme tip of the root, but at a short distance behind it. The reason for this will be readily understood when it is recalled that the root has to burrow through the rough and sharp particles of soil, and hence if the growing cells were at the tip they would be fatally injured. So a protective cap, known as the root cap, surrounds the growing region, to safeguard it from injury as it penetrates the soil and subsoil. The outermost layer of this cap is continually being rubbed off through contact with the soil particles, and at the same time is being replaced by cells produced by the growing region. Then again, if this region were situated in the middle or at the base of the root, the result would be a bending or buckling of the tissue at the tip; so that one realises that these growing cells are in the right spot to perform their function properly. Referring to the cells of the root cap, it may be mentioned in passing that these are covered by a slimy or mucilaginous substance which acts as a lubricant to the root tip and enables it to perform its manifold duties with the greatest efficiency, in much the same way as a touch of oil greatly facilitates the working of a machine. Something in the way of a lubricant is undoubtedly required when the great pressure which roots are capable of exerting, is brought to mind such as the cracking and gradual upheaval of stonework when roots are in contact with a wall.

Before proceeding to deal with the functions of the root, it may be as well to say something of the structure. In outline it is more or less spherical, and is generally brown in colour, save in some cases where it is exposed to light, as in the aerial roots of certain orchids, when it assumes a greenish colour. It has a uniform type of growth, with none of the characteristic divisions of the stem into certain areas which bear no leaves, termed the internodes, and points at which leaves are produced, termed the nodes. This is correlated with the fact that the root bears no leaves or scales, which are in reality rudimentary leaves. In addition it bears, save in the most exceptional circumstances, no buds. It consists of the same elementary organs as the leaf, namely, cells, fibres and tubes. These vary in nature, shape and position according to the functions they fulfil. Here again we have a protective outside

Digitized by Google

ayer, an inner tissue composed of cells loosely arranged, while in the centre there is a central strand or core, made up of conducting cells and strengthening cells. These conducting cells serve for the passage of water carrying salts in dilute solution, which is absorbed from the soil by means of delicate structures known as root hairs, produced by the outer protective layer in certain definite areas. The disposition of the strengthening cells is interesting, as it is related to the various strains to which the root is subject. Under the action of strong winds, roots are called upon to bear a longitudinal strain, as they anchor the plant in the soil, and hence it can best meet this tension if the strengthening cells are united in the centre. In a few cases, such as in plants which act as sand binders—*e.g.*, the marram grass—a certain amount of twisting takes place in these cells; but that is wholly an adaptation to environmental conditions. Like the leaf, and as we shall also witness in the stem, most mechanical adaptation in the plant body has arisen to meet the conditions of the surroundings. Such adaptation has been slowly evolved in response to certain factors, while other structures are hereditary and are passed on from generation to generation.

It has already been remarked that the tendency of the root is to get away from light, and in this as in many other respects, it is wholly unlike the stem. It would appear to be urged by some creative force of which we know little. On this hereditary tendency depends the very existence of the plant, as the organism which is to be fed must plunge its roots into the substance where the food material lies. Thus a mistletoe plant pushes its roots into the living branches of the host tree, while an ordinary plant lives an ordinary life and applies to the soil for food and nourishment. With this inherent characteristic to grow downwards, the organ assumes various forms in response to many governing factors. Probably the greatest limiting factor is the shoot system. It will be readily understood that the root and shoot should be in proportion to one another to secure harmonious working. An example will serve to illustrate the point. If we take one of our large forest trees, such as an oak with its mass of heavy boughs, we find that we have present a strong and deep root system by which the aerial parts are efficiently sustained. A few plants, however, have a root system out of all proportion to their stems, a notable one known to every gardener being the carrot, the farmer may think of lucerne and also probably of a tiny weed whose common name speaks for itself, namely, the rest-harrow. These exceptions, however, go to prove the rule. G. C. T.

GARDEN TECHNIQUE

Notes on the Technical Side of the Garden and the Cultivation of Plants.

FLOWERS

MAKING VIOLETS FRAGRANT.

IN cold weather it is often remarked that violets do not smell so sweetly as one would wish. A very good way of bringing out the fragrance of the little purple flowers is on the following lines. Put the violets in a somewhat shallow bowl with water. Now stand this bowl in a dish of good size. Pour steaming hot water into the dish, and then cover the whole with a big box or a dish cover from the kitchen. Leave for twenty minutes and then take out the violets. It will be found that the warm moist air has had a wonderful effect in bringing out the latent fragrance. Some varieties of violet which are not naturally highly perfumed respond to this treatment in a remarkable way.—S. L. B.

BORDER CHRYSANTHEMUMS.

QUESTION.—Should old roots be protected or left exposed during the wintertime?

Answer.—In the northern counties, especially, it is advisable to afford some permanent winter protection to the roots, either by placing dry ashes around them and among the suckers, and also some dry leaves or litter while severe frosts last. A better plan of course, is to lift the old roots every autumn, as soon as the flowers and leaves fade, divide the roots and plant the best parts in a mixture of loam, leaf-soil and sand in a cold frame till the following April. Then transplant them in their flowering quarters, which should, in the meantime, have been deeply dug, cleaned and enriched with rotted manure.

Question.—Is it really necessary to propagate new plants every year? Are such better than the old roots left in the ground to grow naturally?

Answer.—It is advisable to propagate a few cuttings of each variety every winter. Undoubtedly, finer plants and better flowers are grown from cuttings well treated. Old roots always afford more flowers to a clump, but the individual blooms are, generally, smaller and less richly coloured. The next best plan is to lift the roots, divide them, selecting the strongest outside parts, and retain them for a time in a cold frame. This should be done in every part of the country.

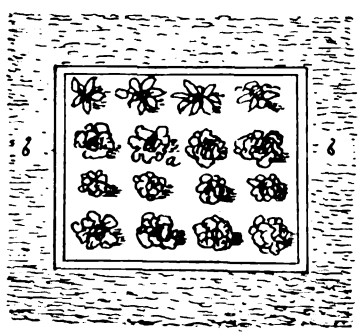
Question.—Will border varieties do as well grown in pots?

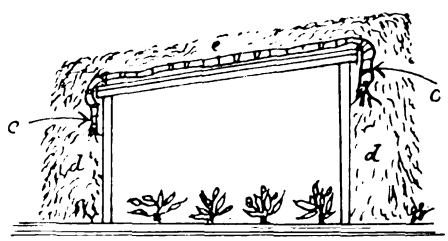
Answer.—No; it is really too hot for the plants in pots at the time of flowering. They may all be so grown, but they need a lot of attention.—GEORGE GARNER.

GREENHOUSE

PROTECTING PLANTS IN FRAMES.

AFTER giving close attention to plants during summer and autumn, we do not wish to lose them in the winter. And the same may be said of seedlings and cuttings placed in the





frames temporarily. During normal winters ordinary coverings will be adequate, but these will be insufficient if very severe weather comes. It is well to be prepared, to have the necessary materials at hand for top coverings and to make the sides of the frames secure at our leisure. I have seen many and varied things used on frosty days at a moment's notice, but not the blanket I was assured a cottager once took off his children's bed to protect some—to his mind—more precious early potatoes. In nearly every garden, or near by, such material as old hay, short straw, hedge bank trimmings and dry leaves is obtainable. About 1ft. from the frame, on each side, drive in a few strong stakes 2ft. apart, one being used at each corner; lay a few branching sticks against these to contain within bounds the dry rubbish packed there tightly; *a* shows interior of frame; *b*, *b*, groundwork of protecting material. On the glass place a mat or mats, their edges coming well over the sides as shown at *c*, *c*, and additional litter is placed on the mat at *e*. As a youth, in many gardens, I had to protect thousands of bedding-out plants in this way in northern counties. The plan always answered, and since, for more than a generation, I have followed it with success. Once tried, this simple way of protecting frame plants will always find favour.—G. G.

GREENHOUSE FLOWERING PLANTS: HOW TO TREAT THEM NOW.

FLOWERING plants are rarely too numerous during the winter months. Those we may possess at the present time, or wish to buy, should be so treated that they will yield flowers freely, pure in colour and over a long period. To this end we should pay very close attention to watering, ventilation, heating and cleanliness: not only cleanliness generally in the structure, but also of every individual plant and truss of flowers, if of this character, on it. We may first refer to zonal pelargoniums. These are splendid all-winter flowering subjects if well treated. Do not despise the single-flowered varieties: they are really first-rate and do not suffer from damping so much as the doubles. But in their case, especially, twice weekly at least, every fading leaf and flower petal should be removed. Of course, in every case morning watering is best; not any repay this attention, however, more than the zonals, and a nice buoyant atmosphere with air circulating about the plants will also do them good. In the case of salvias, all direct draught should be avoided, or the flowers will drop off. The winter-flowering

Digitized by Google

begonias require similar treatment: not a high temperature, but careful watering and only a slight difference between day and night temperatures. Cinerarias and primulas, and also cyclamen, may be treated similarly to zonals. Similar treatment will suit libonias, mignonette and Kalanchoe carnea, the libonias being placed in the warmest corner.—G. G.

TREATMENT OF FORCED BULBS IN POTS AND BOXES.

QUESTION.—Bulbs, when grown in pots or boxes and covered with ashes, make a strong growth. How should they be treated when removed from their covering material?

Answer.—The ashes, sand, earth or other covering material used, should be taken off when the empty inverted flower-pots underneath are likely to cause a crippled spike or flower stem if left in position any longer. On a fine day, or when the soil and ashes are not in a frozen condition, remove all the most forward plants to a cold frame and cover the glass at once with mats, or leave larger, empty inverted pots on the growing bulbs for a week or so.

Question.—Why should this be done and why should the bulbs be placed in a cold frame and not in a warm greenhouse direct from the ashes?

Answer.—Because the sudden exposure of the blanched leaves and embryo-like spike of flowers would cause a very severe check, and most likely the flowers would not develop fully and probably also be deformed. The exposure to full light and air should be gradual. Also, the tender growths must be subjected to a warm greenhouse temperature when their roots are more plentiful and their leaves greener; moderate heat will then hasten the flowering and be generally beneficial.

Question.—When and how should pot bulbs be fed?

Answer.—The best time to feed is when the flower buds are well formed, and the ideal way to apply a stimulant is by placing the pots in saucers filled with a liquid manure, leaving the pots so for one night, then empty away any unused liquid. This method of feeding should be attended to twice each week.—GEORGE GARNER.

STOVE PLANTS: THEIR TREATMENT IN WINTER.

ALTHOUGH many kinds of plants requiring a stove temperature were discarded a few years ago, thousands are still cultivated and are being favoured more and more every year. I am referring to the little specimens those that are so useful for decoration, mainly in spring and summertime, and not to monster specimens, such as we used to admire thirty or forty years ago. They make their new growth from March to August and any cleaning that is necessary during that period must be done with very great care on account of the leaves being so tender. It is during the wintertime that a thorough cleansing of the foliage is possible and advisable. The leaves are firmer and insecticides can be used with more safety and much better effect. Crotons, dracænas, palms, Cyperus alternifolius, coleus, Ficus elastica, pandanus, Stephanotis floribunda and similar kinds are liable to infestation by mealy bug and scale. Sponging with tepid water and the insecticides now, will clear them of such pests and all plants so judiciously treated, will make remarkably good progress the following year. The cleaning work should be done in the structure where the plants are growing. To keep them in a healthy condition a judicious damping of the floor every day is advisable as one is obliged to have the pipes fairly hot in adverse weather. The turves, peat and leaf-soil, intended for the re-potting of the plants in spring, should be prepared and stored now.—HANTS.

MISCELLANEOUS

MOSS ON LAWNS.

DURING damp weather patches of moss are very likely to appear on the lawn. These should not be neglected, as the moss is sure to spread and, in quite a short while, it may kill the grass over wide areas. The presence of moss on a lawn is a sign that the ground is waterlogged and deficient in lime. During the winter rake up the affected parts so as to loosen and break up the moss growth. Then apply ordinary builder's slaked lime at the rate of 4oz. to every square yard. Dressings of soot and nitrate of soda, when the weather is open, will often help in discouraging the development of the moss. If the lawn seems really swampy, it is certain that the drainage is defective and steps should be taken to set matters right. Dig a trench right across the lawn from the highest to the lowest point and carefully remove the turf along the opening. In the bottom of the trench, which should be about a foot deep, place a layer of clinkers or broken bricks. Replace the soil and the turves and make everything firm. A trench of this description will drain the soil for a distance of 3yds. on either side. In the case of an extensive lawn, a number of trenches will have to be made. Now and again the shade from trees will induce moss growth on a lawn. Here the spreading branches should be reduced as much as possible, so that the ground beneath may secure more direct sunshine.—LEONARD BASTIN.

TURF.

THERE can be no denying the fact that, for most potting composts, well rotted turf is best. Turf may be cut and stored at any time during winter, and for our purposes it may be stored about a year; a less time may do and a longer time will do good rather than otherwise.

Turf from an old pasture where cattle have been feeding is best. It should be free from weeds and of a light, porous nature Stack it grass-side down and, if wireworm is feared, put some fresh soot between the layers or wet each layer with a liquid fumigant. It is not a wise plan to add manure unless it is known definitely that this will be required as an ingredient of the potting compost.

All readers cannot get turf and many have to take ordinary garden loam. The upper 6ins. of soil is often too rich for potting, and we would prefer skimming it off to get the second spit; this, again, must not be harsh and barren, nor sour and waterlogged.

Old potting compost may be looked upon as exhausted soil, but it has its uses too. Allowed to lie exposed to the air for a time, the "balls of soil" may be broken with the fork and the roots shaken out. The fine compost which remains is an excellent mulch to use in the open for various purposes. It is fine, free and gritty, as a rule.

Soil for composts should always be taken under shelter some time in advance of needs. It then loses excess moisture and potting can be carried out with better results. The outer skin of a turf heap may be discarded or used to build a new heap; the inside of the heap is excellent.—LANARKSHIRE.

R.H.S. Trials of Roses for Garden Decoration at Wisley.—The Director of the Royal Horticultural Society's Gardens at Wisley wishes to remind all raisers of roses of the trials in progress in the Gardens. Six plants of each new variety should be sent to him as soon as possible addressed The Director, R.H.S. Gardens, Wisley, Ripley, Surrey (Station: Horsley, Southern Railway). The necessary entry forms and further information may be obtained from him on application.

YOU CAN GIVE NO BETTER GIFT

to your friend, either at home, in the Colonies, or abroad, than a weekly copy of
